THE

SOUTHERN CULTIVATOR,

A SEMI-MONTHLY JOURNAL,

DEVOTED TO SOUTHERN AGRICULTURE,

Designed to improve the Mind,

AND

ELEVATE THE CHARACTER OF THE TILLERS OF THE SOIL,

AND TO

INTRODUCE A MORE ENLIGHTENED SYSTEM OF CULTURE.

EDITED BY J. W. JONES.

VOL. I.

AUGUSTA, GA.

PUBLISHED BY J. W. & W. S. JONES.

1843.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., MARCH 1, 1843. No. 1.

AGRICULTURAL LETTER FROM GENERAL WASHINGTON.

We are indebted to the kindness of an old friend for the following valuable document: valuable not only because of the revered source from which it emanates, but because it affords many excellent lessons from an able and practical farmer; it is, too, strongly characteristic of the American hero. We see here the exercise in private life of that attention to detail, that inflexible devotion to order and discipline, which so eminently mark the public character of Washington. No one can read this letter without seeing at once that the writer was an industrious, sound *practical* farmer. He, whose indomitable energy had given freedom to a world, did not esteem the most minute details of agriculture unworthy his attention.

It will probably surprise the reader to find Gen. Washington insisting upon the use of harrows and cultivators in the cultivation of his corn; this we have been accustomed to plume ourselves upon as a much more modern invention.

The letter directed to his overseers, is taken from the manuscript copy in Washington's own hand writing, and, as we are informed, now appears in print for the first time. [*Southern Planter.*

—

PHILADELPHIA, 14th July, 1793.

GENTLEMEN:----It being indispensably necessary that I should have some person at Mount Vernon through whom I can communicate my orders; who will see that these orders are executed; or, if not obeyed, who will inform me why they are not; who will receive the weekly reports and transmit them; receive money and pay it; and in general to do those things which do not appertain to any individual overseer----I have sent my nephew, Mr. Howell Lewis, (who lives with me here) to attend to them until I can provide a manager of established reputation in these matters. You will, therefore, pay due regard to such directions as you may receive from him, considering them as coming immediately from myself. But that you also may have a general knowledge of what I expect from you, I shall convey the following view (which I have of the business committed to your charge) as it appears to me, and direct you to govern yourself by it; as I am persuaded nothing inconsistent therewith will be ordered by Mr. Lewis, without authority from me to depart from it.

1st. Although it is almost needless to remark that the corn ground at the farm you overlook ought to be kept perfectly clean and well ploughed----yet, because not only the goodness of that crop depends upon such management, but also the wheat crop, which is to succeed it. I cannot forbear urging the propriety and necessity of the measure in very strong terms.

2d. The wheat is to be got into the barns or into stacks as soon as it can be done with any sort of convenience, that it may not (especially the bearded wheat, which is subject to injury by wet weather,) sustain loss in shocks----and because the shattered grain in fields may be beneficial to the stock; but no hogs are to be put on stuble fields in which grass seeds were sown last fall, winter or spring; other stock, however, may be turned on them, as it is rooting that would be prejudicial.

3d. The whole swamp from the road from Manley's bridge, up to the lane leading to the new barn, is to be got into the best and most complete order for sowing grass seeds in August----or, at the farthest, by the middle of September. The lowest and wetest part thereof, is to be sown with timothy seed alone. All the other parts of it are to be sown with timothy and clover seeds mixed. The swamp on the other side of the aforesaid lane (now in corn and oats) is to be kept in the best possible order, that the prrt not already sown with grass seeds may receive them either this autumn (as soon as the corn can be take off with safety) or in the spring, as circumstances shall dictate.

No exertions or pains are to be spared at Daguerun to get the swamp from Manley's bridge up to the meadow above, and the two enclosures in the mill swamp, in the highest order for grass, to be sown in the time and manner above mentioned. But that no more may be attempted than can be executed well, proceed in the following order with them accordingly as the weather may happen to be, for this must be consulted, as dry weather will answer to work in the low parts best, whilst the higher grounds may be worked at any time.

1st. Begin with the swamp from Manley's bridge upwards, and get all that is not already in grass, well prepared for it, and indeed sown. 2d. That part of the low meadow on the mill run, which lies between the old bed of it and the race, and within the fences. 3d. After this is done, take that part of enclosure above (which was in corn last year,) lying between the ditch and fence No. 1, up and down to cross fences. 4th. Then go over the ditch and prepare slip after slip as the ditch runs from the one cross fence to the other, and continue to do this as long as the season will be good, or the seed can be sown with propriety and safety.

I conceive that the only way to get these grounds in good order and with expedition, is to give them one good ploughing and then to tear them to pieces with heavy harrows. Whether it be necessary to cut down and take off the weeds previous to these workings can be decided better by experiments on the spot than by reasoning on it at a distance. My desire is that the ground shall be made perfectly clean, and laid down smooth; without which meadows will always be foul----much grass left in them, and many scythes broken in cutting what is taken off.

4th. The buckwheat which has been sown for manure ought to be ploughed in the moment a sufficiency of seed is ripe to stock the ground a second time; otherwise, so far from its answering the purpose of manure, it will become an exhauster. For this reason, if the ploughs belonging to the farm are unable to turn it in in time, those of Muddy hole, Dague run and Union farm, must combine to do it, the work to be repaid by the farm which receives the benefit, as soon as the work is accomplished thereat.

5th. Where clover and timothy seeds are mixed and sown together, allow five pints of the first, and three of the latter to the acre; and where timothy only is sown, allow four quarts to the acre. Let the seed be measured in the proportions here allotted, and put into a half bushel, and the half bushel filled with sand or dry earth, and extremely well mixed together in your own presence or by yourself, which will answer two good purposes, viz: 1st, to prevent theft, for seeds thus mixed, would not sell----and 2dly, the seedsman being accustomed to sow a bushel of wheat to the acre would be at no loss to cast a bushel of this or anything else, regularly on that quantity of ground.

6th. It is expected you will begin to sow wheat early in August, and in ground perfectly clean and well ploughed. I would have, and do accordingly direct that not less than five pecks of seed be

sown on each acre. The plan of the farm over which you look is given to Mr. Lewis, from which the contents of each field may be known. And it is my express direction that every watch and the best attention may be given to see that this quantity actually is put in; for I have strong suspicions (but this ought not to be hinted to them) that the seedsmen help themselves to a pretty large toll.

7th. As soon as you have done sowing and even before, if it can be done conveniently, you are to set heartily about threshing or treading out the wheat; and as fast as it is got out, to have it delivered at the mill or elsewhere, according to directions. The longer this business is delayed, the more waste and embezzlement will there be of the crop. The wheat is to be well cleaned; the chaff and light wheat are to be properly taken care of for the horses or other stock----and the straw stacked and secured as it ought to be against weather and other injuries; and until the whole be delivered, it will require your constant and close attention.

8th. The oats at the farm you overlook, are I presume all cut; in that case, let all the scythes, and cradles, and rakes which you have received, be delivered over to the mansion house; or if you choose to keep them against next harvest you must be responsible for them yourself.

9th. The presumption also is, that the flax is, ere this, pulled; let it be well secured and at a proper season stripped of its seed and spread to rot. During this operation, let it be often turned and examined, that it be not overdone, or receive injury in any other respect by laying out too long.

10th. Get the cleanest and best wheat for seed, and that which is freest from onions. I would have about one-third of my whole crop sown with the common wheat; one-third with the white; and the other third with the yellow bearded wheat. The overseers (with Davy, as he knows the state of his own farm and the quality of the wheat which grows upon it,) may meet and decide among themselves whether it would be best to have some of each of these sorts on every farm; or in order more effectually to prevent mixture, to have one sort only on a farm. In the latter case, the cutting of that which ripens first, and so on, must be accomplished by the force of all the farms instead of each doing its own work. If the seed on one farm was to be sown on another, especially if seed which grew on a light soil was to be sown on a stiff one, and that which grew on a stiff one sown on a light ground, advantages would unquestionably result from it.

11th. The potatoes at the mansion house must be worked by the ploughs from Union farm, and when this is required, it would be best, I conceive, to accomplish the work in a day.

12th. It is expected that the fences will be made secure, and no damage permitted within them by creatures of any kind, or belonging to any body—mine any more than others.

13th. The greatest attention is to be paid to stocks of all kinds on the farms; and the most that can be made of their manure and litter. They are to be counted regularly, that no false reports may be made; and missing ones, if any, hunted for until found, or the manner of their going can be accounted for satisfactorily.

14th. A weekly report, as usual, is to be handed to Mr. Lewis. In this report, that I may know better how the work goes on, mention when you begin to plough, hoe, or otherwise work in a field, and when that field is finished. The increase, decrease and changes are to be noted as heretofore—and let me ask—

15th. Why are the corn harrows thrown aside, or so little used that I rarely of late ever see or hear of their being at work? I have been run to very considerable expense in providing these and other implements for my farms; and to my great mortification and injury, find, generally speaking, that wherever they were last used they remain, if not stolen, till required again; by which means they as well as the carts, receive so much injury from the wet weather and the heat of the sun as to be unfit for use: to repair or supply the place of which, with new ones, my carpenters (who ought to be otherwise employed) are continually occupied in these jobs. Harrows, after the ground is well broken, would certainly weed and keep the corn clean with more ease than ploughs. I hope, therefore, they will be used. And it is my express order that the greatest care be taken of the tools of every kind, carts and plantation implements, in future; for I can no longer submit to the losses I am continually sustaining by neglect.

16th. There is nothing I more ardently desire, nor indeed is there any more essential to my permanent interest, than the raising of live fences on proper ditches or banks; yet nothing has ever been, in a general way, more shamefully neglected or mismanaged; for instead of preparing the ground properly for the reception of the seed and weeding and keeping the plants clean after they come up---the seed are hardly scratched into the ground and are suffered to be smothered by the weeds and grass if they do come up; by which means the expense I have been at in purchasing and sending the seeds (generally from Philadelphia,) together with the labor, such as it is, that has been incurred, is not only lost, but (and which is of infinitely more importacne to me) season after season passes away, and I am as far from the accomplishment of my object as ever. I mention the matter thus fully to show how anxious I am that all the seeds which have been sown or planted on the banks of the ditches should be properly attended to; and the deficient spots made good, if you have or can obtain the means for doing it.

17th. There is one thing I must caution you against (without knowing whether there be cause to charge you with it or not)----and that is not to retain any of my negroes who are able and fit to work in the crop, in or about your own house, for your own purposes. This I do not allow any overseer to do. A small boy or girl for the purpose of fetching wood or water, tending a child, or some such thing, I do not object to; but so soon as they are able to work out, I expect to reap the benefit of their labor myself.

18th. Though last mentioned, it is not of the least importance, because the peace and good government of the negroes depend upon it---and not less so my interest and your own reputation. I do, therefore, in explicit terms, enjoin it upon you to remain constantly at home, (unless called off by unavoidable business, or to attend Divine worship) and to be constantly with your people when there. There is no other sure way of getting work well done and quietly by negroes; for when an overseer's back is turned the most of them will slight their work, or be idle altogether. In which case correction cannot retrieve either, but often produces evils which are worse than the disease. Nor is there any other mode but this to prevent thieving and other disorders, the consequence of opportunity. You will recollect that your time is paid for by me, and if I am deprived of it, it is worse than the robbing my purse, because it is also a breach of trust, which any honest man ought to hold most sacred. You have found me, and you will continue to find me faithful to my part of the agreement which was made with you, whilst you are attentive to your part; but it is to be remembered that a breach on one side releases the obligation on the other. If, therefore, it shall be proved to me that you are absenting yourself from the farm or the people without just cause, I shall hold myself no more bound to pay the wages, than you do to attend strictly to the charge which is entrusted to you by one who has every disposition to be

Your friend and servant,
GEO. WASHINGTON.

IMPORTANT IMPROVEMENT IN SELECTING SEED WHEAT.---In the selection of seed-wheat, take at least six bushels of a good quality, then take a sieve or screen with holes sufficiently large, so that five bushels of the six will pass thro' it. The one bushel that remains will be kernels of the largest size, and this should be used for seed. When this seed is sown and germinates, it will be found that the blades which spring from it will be uniform, and present the same healthy appearance, and will maintain the same equality until the time of harvesting.---Thus instead of having so great a proportion of small weakly stocks start from diseased or pinched kernels, which can never

produce anything but small straw and consequently wheat of an inferior quality, the whole will stand a fair chance to come to maturity, divested of many evils which attend the sowing of grain where sifting is neglected.

But, says the reader, this important discovery of which you speak, don't amount to any thing after all. It has been known for years, that to sift out the small grains from seed-wheat is a good idea, and is now generally practised among our best farmers. I will respectfully ask such, have you ever known sifting carried to the extent I propose? If you have not, you know but little of the real benefits that will result from this discovery and a practice in accordance with its reasonable theory.

I am informed that Isaac Bowles, Esq., of this town, tried the experiment the past season, and the result was what we had good reason to expect, the most perfect growth of wheat he has ever raised. I believe if this practice should be adopted generally by the farmers of this State, the quality and quantity of the wheat crop would in a very few years be increased one-quarter by the simple process of sifting seed in the proportion I have named, and no farmer need be afraid of injuring his seed by carrying the principle to too great an extreme. The improvement is within the reach of every farmer, and he can satisfy himself on this point.

[*Maine Farmer.*

GAPES IN CHICKENS.---Take as much soft soap as will cover the thumb-nail, and mix it with meal dough. Give it the chickens at any stage of the disease. If this fails on the first application it rarely does on the second. [*American Farmer.*

RENOVATION OF SOILS.

It is not my purpose to discuss the question of renovating soils, but to state the result of an experiment in wheat culture. The soil was rather a stiff clay, and having been some thirty-five years in arable condition, and for much of the former part of this time very productive of wheat, it had been, for want of a knowledge of the benefits of the "rotation system," sadly abused. In 1838, it was summer fallowed, having laid the four years previous to sheep pasture, but the crop of wheat which followed was very ordinary, not yielding ten bushels to the acre; which in part arose from the adhesive and clammy nature of the soil, causing the frost to heave a very considerable proportion of the plants on the surface to perish. This is well known to be a very common occurrence, in our climate, with heavy clay lands, if sowed late; but this was not the fact in the last particular, and the growth in the fall was beyond an average. After the crop was harvested, I observed on all parts of the field, numerous cracks on the surface, to a much greater extent than is usual with similar soils. I contemplated giving the field a heavy manuring the following season, and plant with corn; but subsequently changed my plan, having resolved to adopt the course recommended as above, by Chaptal. I consequently applied about twenty-five large cart loads of coarse, unfermented manure, drawn from my sheep barns, to the acre, which was spread no faster than the ploughs would cover. The plants, in the fall, assumed so dark a green, that I was a little apprehensive of the usual rank growth before harvest, which almost invariably follows the direct application of manure to the wheat crop, as well as large disproportion of straw to the berry. But doubtless owing to the great poverty of the soil, these results did not follow. The field averaged over twenty bushels to the acre, which is about the average production of well tilled fallow land, sown timely, and in favorable seasons, in this immediate quarter. The coarse manure had evidently effected a material modification of the soil, as few cracks were distinguishable on the surface, after harvest, showing most clearly, that it was more friable. It is a year ago last spring, since the grass-seed was sown upon it, and a more luxuriant covering of clover, I have rarely seen, than the field now presents; which is another proof of some renovation of the soil, otherwise very much of the clover would have been thrown out by the frost of last spring. It is my present impression, that if this field is permitted to rest for two or three years longer, and then sowed with buckwheat and ploughed under when in blow, preparatory to wheat, in consideration of what has already been done, its original fertility will be nearly restored, and in some measure the adhesive and clammy texture of the soil destroyed.

But while on this subject, I beg leave to enter a protest against applying manure, except compost, directly to the wheat crop, unless as in the above case, when the soil is rendered quite unproductive, by long and "skinning" management, before agricultural periodicals taught us better. You will permit me to quote your remarks, gentlemen, on this point; for I am quite sure they cannot be kept too much "before the people," from the 7th volume of the Cultivator, taken from a sterling article on "Wheat Culture."---"One of the greatest evils of direct manuring for the wheat crop, arises from the liability of the grain so manured, to lodge. The rapid growth of the stem, renders it unable to support its own weight. It is soft and flexible, contains much less silex than those grown in a poorer soil; the wheat does not usually perfect its berry, and at all times, from the thinness of the skin or cuticle, it is more liable to mildew and rust. These things render it certainly unadvisable, unless the land is very poor and reduced, to apply unfermented manure to wheat." My own experience, as well as thousands of others, in times past, will attest the truth of these remarks. As nearly as possible my practice conforms to the "rotation system;" and I apply my manure in an unfermented state, to my corn and potato crops, and top-dressing of meadows.

L. A. MORRELL.

PRESERVATION OF PEACH TREES.

Having to a certain extent succeeded in the cultivation of the peach in limestone soil, generally considered uncongenial to its growth, I forward by your request a short account of the method of cultivation and mode of nursing adopted.

The orchard, consisting of about fifty trees, was planted in the spring of 1836. At the time of planting, the ground was in grass, but was then subjected to the action of the plough, and has since been thoroughly tilled every year, yielding alternately heavy crops of sugar beets, potatoes and ruta baga. The trees have also been examined once, and sometimes twice a year, for worms, but have not generally been much infested by them.

This comparative exemption is no doubt in consequence of the various alkaline substances which have been successfully used. The most remarkable and immediate effect has followed the use of what is termed "fallen lime," fresh from the kiln; which, when applied in the proportion of about half a peck to the roots of unhealthy trees, and covered with earth, has restored a healthy color to the leaves; and trees which did not look worth a week's purchase have produced fair crops of good fruit in after years. Ashes from anthracite coal have also been applied with very good effect. These applications have usually been made in the spring, but occasionally later in the season. This year wood ashes were used in June with a marked benefit. Soapsuds have also been applied to advantage. In fact, any substance, which by its caustic quality is destructive of insect life, must be beneficial, provided it be not applied in quantities sufficient to injure vegetation. It is an interesting and encouraging circumstance, that several substances combine the properties of destructiveness to insectiverous life, with a direct and positive stimulating effect upon vegetation. In illustration of this fact, my friend Dr. Noble has applied oil soap to a portion of his extensive peach orchard, in the State of Delaware, to manifest advantage.

The mild weather of January and February will sometimes bring forward vegetation, so that the peach trees are liable to blossom prematurely. An attempt has been made to obviate this difficulty, by covering the roots about the body of the trees with wheat straw, when the ground is deeply frozen in winter. This process, by retarding vegetation, has secured them from the danger of the late frosts.

MORRIS LONGSTRETH.

IMPROVEMENT OF SANDY SOILS.

The Hon. W. Clark, of Northampton, has been the great pioneer in the improvement of sandy soils, and from the successful results he has achieved, we may fairly class him among the great agricultural reformers of the present day. He has already given to the public the theory of his operations, which we hope to find room to lay before our readers at some future time. Our object now is simply to give his practice, and after our farmers have begun the good work of reclaiming their almost barren wastes, it will be a pleasure for them to look into the *modus operandi*, and see the reasons of their success. There are three essential features in this practice, and the simultaneous adoption of each is essential to effect the desired object. The first is the frequent and thorough use of the roller; the second, a constant covering of crops on the ground; the third is the introduction of clover and grass as a fertilizer. To illustrate this, we give the history of a single field of some forty acres of worn-out sandy soil, in the vicinity of N. This field was purchased by Mr. C. some eight or ten years since for nine dollars per acre, while the fertile bottom lands, on the other side of the town, would sell readily for $150 to $200. His object was first to get a crop of corn if possible, and the land being too poor for this, he carried on to it a moderate quantity of peat or swamp muck, which was found in the low places on the same field. We may observe in passing, this peat and muck exist to an almost unlimited extent throughout New England, and we consider it of vastly more intrinsic value to the community than all the gold mines that have dazzled the eyes of our Southern neighbors for the last fifteen years. With this dressing, say of fifteen to thirty loads to the acre, the whole cost of which consists simply in digging and throwing into heaps, to be drained, and acted on by the atmosphere, after which it is carried either by carts or sleds in winter on to the adjacent ground; the land is then ploughed, and whatever scurf, sand grass, rushes, mosses, pusseys and briars there may be on the land are turned under, and such is the digestibility of the soil, all these raw materials are at once converted into humus or geine as food for the required plants. This sandy soil has the stomach of an ostrich, and if it cannot, as that voracious biped has the credit of doing, digest old shoes, iron spikes, and junk bottles, it can dissolve and convert into vegetable chyle, whatever organized matter is given to it. The effect of this comparatively slight dressing yielded a first crop of some thirty bushels of corn to the acre, enough to pay for the first cost of the land, and the whole expense of producing it. But while the corn was growing, say from the 20th of July to the 10th of August, rye with red and white clover seed was sown, and the corn being so planted as to admit of harrowing two ways, or even four if necessary, it was well got in with the harrow, and the ground being amply protected by the corn during the sultry weather of this season, the new seed took a vigorous start, and as soon as the corn was somewhat matured, it was cut and carried off the ground, and the new growth then had the entire possession. The roller was then thoroughly applied, as also in the following spring. The early sowing gives strength to the roots of both rye and clover, and renders hazard of winter killing either, especially the clover, much less. When from any cause he is prevented from sowing the clover early, it is omitted till early in the following spring; a postponement that should be avoided when possible, as it thus loses a year's time, requiring another season to mature. The rye is cut the following summer, when the clover is suffered to remain, shedding its seed upon the ground for a successive crop. The following season, if in a proper condition, it is again put into corn or rye according to its fertility, and the course is again renewed. The land, however, usually requires an additional season in clover, and sometimes more, to give the requisite fertility. Mr. C. showed us a field, which from the originally poor condition described, without the addition of any manure or peat or muck, has produced him five crops in seven years, the last, which he had but just taken off, yielding seventeen bushels to the acre. This, it will be readily admitted, is a large crop for poor land, and much beyond the average yield in New England. The growth of the clover on this field, of this spring's sowing, was promising in the highest degree, and as evenly set as in the best land, giving every promise of a large crop the next season, which of course is designed to be added to the soil for its future improvement. When the land is first put into use, (for Mr. C. has several other similar fields which have been variously treated, though always on the same principles,) and it is too poor to produce a paying crop of corn, and he has not time to add the muck, he turns under the surface vegetation, and puts on a crop of rye, always accompanying this with the clover, and after one year's crop from this last, he never fails in a fair yield of corn. On a field thus treated, without any dressing of muck, he got twenty-seven bushels of corn per acre for the first crop, and after an interval of another season, obtained thirty-three bushels on the same land, showing a decided increase in the productiveness of the soil. A slight dressing of plaster is generally, though not always, used, and never exceeds half a bushel to the acre. Mr. C. admits that more plaster might be useful; we think one or two bushels per acre would be applied with decided advantage, but it is purchased at a high price, about $10 per ton, and as economy and a self-sustaining policy has been a prominent principle in this system, this is all that has thus far been afforded. The muck would in all cases be a valuable, remunerating addition, but this he has not always the time to give, and at the prices he has paid for his land, he can afford to leave it once in two or three years in clover, by which it is renovated, and for the present perhaps this may be the most judicious plan. As lands become dearer, however, which they are rapidly doing under this management, they being now worth $20 to $30 per acre, of no better quality than such as he bought a few years since at $8 to $12, the policy of manuring will become more expedient, though the rapidly improving nature of this system will give greater efficacy to the clover crop as a fertilizer.

It is surprising to see the elevated noles and barren planes, that so lately exhibited nothing but a crawling sand, by the operations of the clover roots in this otherwise impracticable material, gradually changing its inadhesive character to a firmly connected mass, showing a furrow slice that would gratify the most practised eye. Mr. Clark acknowledges his surprise at the facility with which the clover takes, and attributes it mainly to the use of the roller. We are inclined to concede much to that instrument, but think for his white and other clover he is greatly indebted to the plaster. Of this we have more to say hereafter.

We observe the woodchucks, who are arrant epicures and gourmands in their selection of esculents, and especially of sweet and abundant clover fields, are thoroughly colonized over all the fields of Mr. C. They follow him, as our politicians do the successful candidate of executive dispensations for John Randolph's seven principles, the five loaves and two fishes. They snuff his green patches of trefoils, and instanter abandon the poverty-stricken fields of his unthrifty neighbors. His crop of woodchucks, though not as important as the *shoe crop* at Lynn, may soon be well worth the harvesting.

Mr. C. has not pursued this cultivation sufficiently long to have matured a system of rotation, which, however, he virtually practices with some variations, from his own judgment. A little more experience will enable him to determine whether a crop can be taken more advantageously every second or every third year; but we are satisfied with a moderate dressing for the corn, the rotation might be of three years' duration, affording alternately corn, rye, and clover, the last to be added entire when dry, to the soil, for its improvement. Green crops are never used as improvers, they always being allowed to mature before turning under. Plaster should always be added, unless ashes or lime can be more economically applied; but the former is limited in supply, and the latter is to be had only at a price which will effectually prevent its use in this region.

Here, then, we have a system for reclaiming barren wastes within every one's reach; costing nothing, and yielding a great deal; and if this were rigidly carried into practice, how soon should we see the naked sand banks that exist to a greater or less extent, every where between the Alleghanies and Atlantic, converted into verdant, luxuriant fields. Yet for the want of the application and steady perseverance in this plain, straight-forward, simple course, how many will continue to live on in ignorant poverty, when they might with less toil, and the use of a moderate share of intelligence, have a competency. A single bar left down in this practice, lets in the whole herd of Pharaoh's lean kine. Without the roller and plaster you get no clover; if you cut off the clover when grown, you get no subsequent crop; or if you crop too closely or rapidly, the clover-bearing properties of the soil are exhausted, and new manures, or years of idle, wasteful fallow are necessary to resuscitate it; whereas, by a careful observance of the above plan, the ground is constantly and profitably at work, bearing its burdens on equitable shares, giving one-half or two-thirds to you, and reserving the remainder to itself, to enable it to continue the supply. Though Mr. C. does not connect any grazing or stock-feeding with these operations, it is easy to see how it can most advantageously and profitably be associated with them. Cattle and sheep can be put on to the rye fields both in the fall and spring, when sufficiently thick and stout to justify it, and when well sodded over with clover, what more mutually advantageous to cattle and land than such a copartnership.

We must add a word for the benefit of such of our readers as have no sandy or sterile soils, nothing but virgin fertility, falsely estimated to be exhaustless. We beg all such to consider that the principles for reclaiming, are the principles for preserving also; that no land is so rich but that it can be exhausted, unless fed by inundations, and that there is more profit in sustaining their lands in the highest condition of fertility, than by a wasteful system of cropping, first to reduce them, to be resuscitated again by slow and painful efforts, or abandoned to posterity to be gradually reclaimed by the sure, though dilatory operations of nature, to that state of fertility in which they might easily have been preserved.

There are some particular advantages that attach to the tillage of light sandy soils. They require the least possible effort to plough and harrow, and these operations can be performed at all seasons when not frozen; no season is too wet, too late, or too early for them. They require no underdraining, and the food for vegetables, in whatever shape it is added, however crude and indigestible, is immediately converted into pabulum for the required crop. The amount of corn and rye afforded per acre would not satisfy a western farmer, and very properly too, but he must recollect that his prices seldom exceed one-half of those obtained at the east, rye and corn being worth usually sixty to ninety cents per bushel, and the straw and stalks go far towards meeting the cost of cultivation. The luxuries also, of good buildings, which are always to be had for less than cost, good roads, schools and churches, and all the accompaniments of a matured and well ordered society are at hand, and are cogent reasons for reconciling the reflecting mind to the absence of that superabundant fertility which so universally characterizes the West. [*American Agriculturalist.*

Pumpkins.—Early in April I ploughed a small field, deep and close; threw abought eight buckloads of barn-yard compost broadcast to the acre, and forthwith planted pumpkin seed at five feet distance in checks. I cultivated as corn until the middle of May, when the ground was pretty well covered in the more luxuriant spots of the vines. I then took hoes in hand and planted, in the replanting manner, corn in each pumpkin hill----the corn having remained in soak forty-eight hours. It came up at once, grew off kindly, and yields a fair crop of corn ----no vacant rows----corn in all.

Previously the pumpkin vines got such a start they were not checked by the growth of the corn, and now exhibit a small field more abundantly bespeckled with pumpkins, than any I ever saw by fourfold. My neighbors seldom pass without inquiring how I raise so many pumpkins and a fair crop of corn together? I tell them frankly the mode of culture, and the pumpkins show the result. I am astonished at my success; my little field----I ought to call it patch----is the admiration of all, and if this short account of the matter should be the means of helping my brother farmers to a like success, the end in view is obtained.

Parvus Agricola.
[*Nashville Agriculturist.*

Salting Horses.—A curious fact is mentioned in Parker's Treaties on Salt: "A person who kept sixteen farming horses, made the following experiment with seven of them which had been accustomed to take salt with their food. Lumps of rock-salt were laid in their mangers, and these lumps, previously weighed, were examined weekly, to ascertain what quantity had been consumed, and it was repeatedly found that whenever these horses were fed on old hay and corn, they consumed only from 2 1-2 to 3 oz. per day, but that when they were fed with new hay, they took 6 oz. per day." This should convince us of the expediency of permitting our cattle the free use of salt at all times, and it cannot be given in so convenient a form as rock-salt, it being much more palatable than the article in a refined state, and by far cheaper. A good lump should always be kept in a box by the side of every animal, without fear that it will ever be taken in excess.

[*Farmers' Cabinet.*

Application of Manure.---The most essential point in my estimation is not thoroughly looked at, viz: the making of the most of our manure after once made. Some say put it where you are going to plant corn or potatoes, and plough it under, and it will ferment and rot, and as the soil is thirsty it will absorb it. So it will for a season; but as you plough and hoe, you stir up the manure and leave it exposed to the scorching sun, and it evaporates and is wasted. The spring following, you plough and sow the same field with oats, as is generally the case; and here you not only expose the manure, but the first crop, after it is well mixed with the soil, is one calculated to impoverish it the most. Then comes a crop of rye or wheat, which, with your oats and corn, exhausts three-fourths of the manure. Thus in my estimation this three-fourths is lost to the farm.

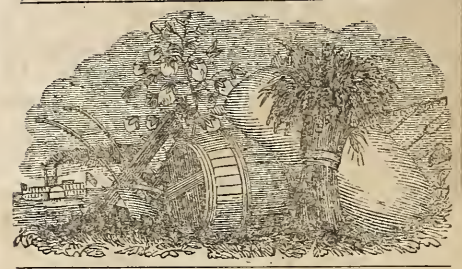
The question then arises, what shall we do with our manure? Why, sir, I would advise to put it where you sow rye or oats, and plough it under, and let it stay there, and sow grass-seed for your first crop, and smooth it down to meadow or pasture. Then you would have large crops of grain and grass for fodder and to make manure with, besides the compost heap. Then you will have a rich meadow pasture for your planting, instead of a plough-worn field that needs thirty or forty loads of manure to be fit to till.

[*Farmers' Gazette.*

Relief of Choked Cattle.—I find in your October number, a receipt by David F. Lott, to relieve choked cattle. I some months since sent to the Agriculturist, Nashville, a receipt, and in a few weeks after its publication, received the thanks of a gentleman, who, by using the prescribed means, saved a fine horse, after trying all other means recommended without effect. Raise one of the fore feet as the smith does when shoeing a horse, tie a strong cord, whip-cord or drum-line will answer, tight above the knee, while the foot is up; let the foot go, and if the animal refuse to put it to the ground, as it probably will, a smart stroke with a whip must be dealt, and in a second the beast is relieved; be careful in tying the string to tie a slip knot that you can loosen quick, for the pain is excruciating. How it operates is immaterial; my theory, probably a false one, is this: the hard cord, acting on the nerves of the arm, produces nausea, the muscles of the throat are relaxed, and the substance by which the brute is choked is thrown from the gullet. John A. Jones.

Fairie Knowl, Geo., 1842.

Cultivator.



WEDNESDAY, MARCH 1, 1843.

TO SOUTHERN PLANTERS.

In obedience to a promise made some time since, we have entered upon a new enterprise, and to-day send forth for your inspection, and, we fondly hope, your approval, the first number of the "Southern Cultivator." In commencing a work of such importance to the cultivators of the soil, we have been influenced by no other motives than to contribute our humble but zealous efforts to the restoration of the exhausted lands of the country, to introduce an enlightened system of agriculture, and to afford an acceptable medium for the interchange of views between planters, upon a subject in which all classes of society are so deeply interested. We have seen and felt the blighting effects upon the interests and independence of Southern planters, which have been produced by the too common and fatal system of Agriculture almost universally adopted, and it has long been to us a source of deep anxiety. To correct the evils of a system so long established and practised upon, and to introduce one better adapted to the wants and comforts of the whole population, we are fully aware, is a work of no ordinary labor, both physical and mental; but when we reflect upon the important advantages which a proper direction of our energies promises to develope to the great agricultural interests of the South, we enter upon the duties with the highest confidence of success, relying for aid upon those who have embarked in this valuable and interesting pursuit. To the Planters, therefore, of Georgia and the surrounding Southern States, do we appeal for aid in this enterprise—we ask not only their influence in circulating the work among all the tillers of the soil, but, as we hope and believe that it will derive its chief interest from an interchange of their views upon all subjects pertaining to agriculture and the general business of the farm, we invite their cordial and sincere co-operation in forwarding to us their views, and the result of experiments in every department of this deeply interesting branch of industry. It is our purpose to make the "Southern Cultivator" a work worthy of the great cause in which it is engaged, and to which it shall be specially and exclusively devoted, and we sincerely hope that no man who feels an interest in the introduction and promotion of an enlightened system of culture for our great staple products, will withhold his zealous support. With this brief introduction, we commit the work to the hands of those for whose especial benefit it has been undertaken, not doubting their readiness to unite with us cordially in a zealous and energetic effort to accomplish whatever the most sanguine friend of the cause may anticipate.

GIVE US YOUR AID.

This number of the "Southern Cultivator" will be sent to Postmasters, and other citizens, in every section of the State, and to many in the adjoining States, who are not subscribers, and we most respectfully ask them to exhibit it to their neighbors and friends, and solicit subscriptions. To all such as may receive it, therefore, we desire to say,

We send you the "Southern Cultivator," believing you feel a sufficient interest in the cause of Agriculture, to lend your aid in giving it a general circulation among the planters in your immediate neighborhood. The work, as its title imports, will be exclusively devoted to Southern Agriculture, and whatever pertains to the business of the Agriculturist, in all its varied departments; and, in order to place it within the reach of the most humble tiller of the soil, the subscription price is only ONE DOLLAR per year, ALWAYS IN ADVANCE. If it please you, sir, to contribute your aid, we shall feel grateful for the courtesy, and hope you will be abundantly compensated by the great good it will accomplish.

In presenting to the planters of the South, the first number of the "Southern Cultivator," which circumstances beyond our control have delayed to a much later period than we anticipated when our prospectus was first issued, we desire to remark, in all sincerity, that the very limited patronage as yet bestowed, is not sufficient to justify our making the work what we hoped to do when we determined to embark in the enterprise, and what every Southern man would be pleased to see it. To render it a work worthy of the noble cause in which it is engaged, and every way acceptable to the agriculturists of the country, much money must be expended in the procurement of drawings, and cuts of the various implements of husbandry and animals, necessary to be thus illustrated for the satisfaction of the readers of the work, and for the attainment of the greatest possible good to society.—Relying, therefore, exclusively upon the subscription list to be reimbursed in this expenditure, it is equally a matter of interest to us, as well as the patrons of the work, that it should have an extensive circulation, which can alone defray the expense. While, then, we assure those who have already promptly entered their names upon our list, that we shall proceed with the publication of the present volume to its completion, and shall devote our best energies to make it valuable and useful to every man who may read it, if he cultivate but a single half acre of land, though we add not another name to our list; nevertheless we submit to them, whether, as a matter of self interest, they should not use some exertion to obtain for it a large circulation.

CHANGE OF NAME.

Since our prospectus was issued, we have discovered that in adopting the name of "Southern Planter" for our paper, we have encroached upon the rights of our brethren of Richmond, Virginia, who publish an agricultural work under that name. We have, therefore, to avoid any such collission, adopted the name of "Southern Cultivator," which is equally comprehensive and adapted to the character of our work, in which name it will be published.

TO CORRESPONDENTS.

In another article we have invited our friends generally to furnish us with whatever they may deem of sufficient interest to the great brotherhood of planters to be published, and we trust that none will require a special or more particular solicitation; for while the "Cultivator" will be a medium of communication between agriculturists themselves, we desire to make it likewise so between our correspondents and ourselves, we shall thereby save much labor and avoid the expense of postage.

REPORTS OF THE MARKETS.

Since our prospectus was issued, the inquiry has been several times made of us, "whether the Cultivator would contain reports of the markets," &c.? to which we reply, that during the cotton season, which covers nearly the entire year, we shall regularly report the value of our great staple, together with such other information as we shall deem of interest to the planters—all of which will be collected from the most authentic sources. We shall also, in obedience to the suggestion of numerous friends, report regularly the value of money, particularly while we have a depreciated circulating medium in the State; but as we hope the day is not far distant when such a currency will be driven entirely from circulation, we think that such a report may, in a short time, be dispensed with; however, until it can be, we shall continue to give it, believing that no information is more valuable to the planter than to know the value of the money for which he exchanges the products of his labor.

HANCOCK PLANTERS' CLUB.

In another part of this paper will be found the report of the proceedings of this Club at its late Annual Fair, for which we are indebted to the Georgia Journal. In presenting this paper to the consideration of the planters of the South, we would most respectfully urge the importance of forming similar societies in every county, as one of the first steps in the great work of improving Southern Agriculture. Had we space, we would extend our remarks in support of the necessity for the formation of such societies, and the benefits which must certainly result from them, but for the present we are compelled to defer them, and in the mean time would suggest to the Executive Committee of the Hancock Club, the propriety of allowing us to publish their Constitution and Bye Laws, which we will do most cheerfully if a copy be furnished.

Errata.—In this article three errors appear, which were discovered too late to make the correction. Under the head "Swine," in the first line of the second paragraph, and in the eighth and eleventh lines of the last paragraph, the name "A. E. W. *Bonner*," and "Mr. *Bonner*," should be "Brown."

GEN. WASHINGTON'S LETTER.

We know not that we can render a more acceptable service to our readers than we do in presenting to them, in this number, the letter of Gen. WASHINGTON, which so happily illustrates the true character of the "FATHER OF HIS COUNTRY," and deserves to be preserved as an enduring monument of his true greatness.

☞The reader will perceive that we have been compelled to rely, for the matter in this number, almost exclusively upon our exchange list, which is as yet very limited. We hope, however, in our succeeding numbers, that our correspondents will enable us to present much original matter, and particularly adapted to the objects of our enterprise.

PLOUGHING UNDER CLOVER.—On reading in your number for the present month the inquiry of your correspondent of Selim's Grove, Pa., and your answer, on ploughing under heavy clover, I could not resist the inclination to tell you what I know about it. On experiencing the same difficulty mentioned by your correspondent some years since, I studied for and found a remedy, viz: to the beam of Prouty's or Ruggle's & Nourse's plough, attach a circular cutter 8 inches in diameter. In land clear of stone, a cast-iron one is as good as any. Mine is 1½ inches thick in the centre for 2 inches of the diameter; then ¾ of an inch, tapering to an edge. In stony soil, a ring of steel is made and put in the mould, and the centre cast on it. The pin in all plough-wheels should be cast steel.—I do not know but the "star cutter" I saw at your office would do, but think not. Near the end of the beam attach a heavy chain; the other end doubled on itself, should trail in the former furrow, and will bend the tops of any green crop so as to cover them. I have seen Moore & Barnaby's plough work. It does well, but not as smooth as either of those above mentioned. I think Yankee ingenuity could attach the wheel to that in such a mode as to do the work required. My plough does not clog twice in half a day on an average. The wheel walks directly through three inches of the surface, cutting all before it. JAMES BATES.

NORRIDGEWOCK, Me., Oct. 11, 1842.

[*Cultivator.*

MAKING VINEGAR.—We have never found any difficulty in making good vinegar from cider when we have drawn it from the lees after the fermentation was wholly over, and placed it in a place where the temperature was higher than it is in the cellar. Left on the lees, or in a low temperature, the acetous fermentation is rarely complete. If our correspondent will place his cider where the temperature is from 65 to 80 degrees, and draw a pailful daily from each cask, to be returned by the bung-hole; or if he will procure from a cask of good vinegar a quantity of the substance called mother of vinegar, and add it to a cask we think he will soon have vinegar. There are in London extensive vinegar factories managed in this way. The casks are placed on end, and the tops made full of holes. On each is placed a bucket or tub, containing about half a bushel of inferior or Malaga raisins. A man is constantly employed in passing around the rooms, which are heated to 75 or 80 degrees, drawing a pailful from the bottom and pouring it upon the raisins, from which it enters the cask. This gives the wine-flavor and body. If the cider is too weak, sugar is added. The vinegar is first-rate in a fortnight.—*Cultivator.*

CEMENT TO MEND BROKEN CHINA OR GLASS.—Garlic stamped in a stone mortar; the juice whereof, when applied to the pieces to be joined together, is the finest and strongest cement for that purpose, and will leave little or no mark if done with care.

CULTIVATION OF CLAY LAND.

Our principal object at the present moment, is to give some general directions for cultivation of clay lands, as they are usually found in this country, which are the results of long-continued, skilful practice of the best farmers. The most desirable improvement would be to alter the texture of this description of land, by the addition of a quantity of sand and gravel so as to modify the tenacious character of the clay. This plan, however, like that of under-draining, is too expensive for this country, except in the neighborhood of cities, where land is sufficiently valuable to justify the cost; and improvement in this way must be confined to such lands, or small patches elsewhere, where sand is convenient for the purpose.

Another mode of improvement, which to a certain extent, is within every farmer's reach, and is one of the legitimate objects of every good farmer's system, is to add large quantities of coarse, unfermented manure, and all his undecayed vegetables; which may be done on a large scale, by turning in matured crops produced upon the land. There is no danger of putting on too much manure of this kind, if buried sufficiently deep, in proportion to the quantity used. And there is as little danger of suffering any loss of the manure. It will last till exhausted by the growth of vegetation. Nor will it burn the land, according to the common phrase, as an excess of manure does on light and sandy soils. It is not carried away by rains, or evaporated by heat, but like coin, securely hoarded in a strong box, it is safely retained till the owner's key is applied to unlock it. The mechanical, as well as chemical character of this soil, particularly adapts it to the preservation of manures; for in addition to its strong chemical affinity for ammonia, which is the fertilizing principle in all soils, its mechanical structure enables it to hold, beyond the possibility of escape, all the animal and vegetable substances buried beneath it.

After doing whatever can be effected advantageously towards altering its character by under-draining, the next process is to put the surface into the right shape. This should always have some descent, sufficient to enable the water to pass off freely. When the natural surface has not declivity enough to effect the object, the land must be thrown into beds of 10 to 20 feet wide, with a deep, double furrow between each to conduct off the water, which falls from the more elevated surface; and the water accumulated in these furrows should be led away through some natural ravine or artificial ditch.

For all grain crops to be sown in the spring, the land should be ploughed the preceding fall. The following spring the grain may be sown directly upon the surface, and harrowed in and rolled, without allowing the plough to touch it. By this operation we have the bed in which the grain is to nestle, and from which it is to draw its future support, more finely divided by the elements, and the action of frost through the winter, than can be done by any instrument whatever, and no alteration of this handiwork of nature can be made out for the worse.

If corn or roots are required, the land should be half ploughed the previous fall; that is, a space should be left unmolested, of the width of a furrow, on which the upturned furrow is thrown. By this operation a large dry surface is exposed to the salutary effects of air and moisture, heat and frost; and it will be in the best possible condition for early tillage, and abundant crops. It will be mellow, friable, and comparatively dry, and by thorough cross-ploughing harrowing and rolling in the spring, it will be well fitted for the reception of the seed.

For winter wheat we do not think them suitable, unless prepared by thorough under-draining, as the wheat is very generally winter killed, or thrown out by the frost, or drowned by excessive rains, before the sun gets sufficiently high to protect it. But with the best varieties of spring wheat, it produces largely. For the production of rye, it is totally unsuited; but of barley, oats, peas, grass and roots, when suitably prepared, no soil produces better crops. Their chief value however is for grass lands, and when properly put down in meadow, they ought never to be disturbed, as with good management, they will be in a constantly improving state, and afford the most profitable and remunerating returns. But while in this condition, no animals should ever be suffered to graze them, and especially while the ground is soft. Poaching is destruction to them, and no scarcity of other food will justify the farmer in driving his cattle upon his meadows while saturated with water. It is a common opinion by those unaccustomed to them that clay lands will not produce good clover; yet we have never seen better clover, or larger crops, than we have repeatedly raised on them.

When required for roots, corn, or other hoed crops, the soil should be well charged with manure, and the most thorough tillage will be amply repaid. "A little land well tilled," has a peculiar signification when applied to this kind of soil. Plaster, (sulphate of lime) has no appreciable effect on it when applied in small quantities; and lime, (carbonate of lime,) has less than on any of the lighter soils. Ashes are valuable on any land, and, we believe, under all circumstances; yet we have repeatedly made the application of them on a very stiff clay, without deriving any immediate perceptible benefit. A longer time is required under certain circumstances, for them and other manures to act, but their action continues through a much longer period.—*American Agriculturalist.*

A CHEAP PAINT.—Take one bushel of unslacked lime and slack it with cold water; when slacked add to it 20 pounds of Spanish whiting, 17 pounds of salt, and 12 pounds sugar. Strain this mixture through a wire seive, and it will be fit for use after reducing with cold water. This is intended for the outside of buildings, or where it is exposed to the weather. In order to give a good color three coats are necessary on brick, and two on wood. It may be laid on with a brush similar to whitewash. Each coat must have sufficient time to dry before the next is applied.

For painting inside walls, take as before, one bushel unslacked lime, 3 pounds of sugar, 5 pounds salt, and prepare as above, and apply with a brush.

I have used it on brick, and find it well calculated to preserve them—it is far preferable to oil paint. I have also used it on wood, and assure you that it will last longer on rough siding than oil paint will on planed siding or boards.

You can make any color you please. If you wish a straw color, use yellow ochre instead of whiting; for lemon color, ochre and chrome yellow; for lead and slate color, lampblack; for blue, indigo; for green, chrome green. These different kinds of paint will not cost more than one-fourth as much as oil paints, including labor of putting on.

[*Ontario Freeman.*

BEES.—The best place to put bees in is a dry, cold and dark room or outhouse, if it can be obtained. The colder the winter the better, if the air is dry. Damp cold gives bees the rot. Put your bees there the last week in November, and let them sleep quietly till the flowers begin to come out in the spring. In Switzerland a whole village clubs together, and hires a cold dry room which they darken and put all their bees in.

We find the above in an exchange paper, and think the system recommended at least plausible. So long as bees remain torpid they do not eat; and to keep them in this state, the temperature of the place where they are kept must be low; it must also be dry, or the mass of bees and comb will become mouldy. Bees die in multitudes by being enticed out of their hives in sunny days, before they are able to obtain food, or get back to their hives.

[*Albany Cultivator.*

ANNUAL FAIR OF THE PLANTERS' CLUB OF HANCOCK.

SPARTA, November 4, 1842.

The Executive Committee of the Planters' Club of Hancock transmit to you, for publication, the following report of the proceedings on the day of their Annual Fair. The Club convened at the usual hour, at the Court House, and after the transaction of the ordinary business, formed a procession with the large concourse of citizens and gentlemen from neighboring counties, who were assembled to witness an exhibition so novel in its character to Georgians generally, and proceeded to the Female Academy, in which spacious building the crowded audience listened to a very interesting address, for more than an hour, delivered by the Hon. GARNETT ANDREWS, an honorary member of the Club. The utmost harmony prevailed through the day, and a laudable spirit of emulation and rivalry was manifested by the various competitors for premiums.

The following premiums and honors were awarded by the Club:

To Miss A. L. Kelly, for the best piece of domestic cloth for gentlemen's wear, a premium of $3.

To Mrs. J. P. Whitehead, for the second best do., 1st Honor.

To Mrs. R. S. Hardwick, for the third best do., 2d honor.

To Miss Amelia Kelly, for the best domestic Counterpane, a premium of $2.

To Miss Delia Kelly, for the second best, (wrought,) 1st honor.

Mrs. Whitehead exhibited a piece of very handsome black jeans, and Mrs. Hardwick some handsome vesting, and 9 lbs. of excellent butter.

To Mrs. Hardwick, sen., for the best pair of domestic hose, a premium of $1.

To Miss Rebecca Bass, for the best ladies domestic dress, a premium of $2.

To Miss Sarah Bass, for the second best do., 1st honor.

The above elegant dresses were made of silk raised by the family.

Three handsome capes were exhibited, the best by Miss Bass, the second best by Miss Smith, and third best by Mrs. Henry Griggs;—also, two Capes, the best by Mrs. Griggs, the second best by Mrs. Howitt;—also, two work pockets, the best by Miss Culver, the second by Mrs. B. Amos. Miss E. Sperting exhibited a very beautiful Cape, an imitation of fur, and a set of domestic bed-curtains. No premium was offered on the above articles.

Messrs. Watkins, Hart & Co., exhibited some very beautiful specimens of tin ware, and a superb bathing tub of the same material.

Mr. Howit, a pair of fine harness, and Mr. James Smith a dozen bottles of excellent wine, from the Scuppernong grape, and presented the same to the Club. Several agricultural implements were also shown. Among them a turning plough attached to an iron stock, by Mr. John T. Martin; one by John Mundain, designed for a wood stock, and by Mr. Wm. H. Sayre, a drill barrow, two harrows and a roller.

HORSES.

To Thomas Neal of Warren, for the best Stallion, by Pennoyer, his dam the celebrated mare Nubbin, a premium of $5.

To S. A. Pardee, for the 2d best do., Martin Jackson, by Jackson, dam Decatur, he by Sir Charles, 1st honor.

To Abraham Williams, for the 3d best do., by Jackson, dam by St. John, 2d honor.

To George W. Culver, for 4th best do., by Jackson, 3d honor.

Many other fine Horses were shown, but not for premiums, by their public spirited owners, of fine form, action and condition. Among them was Thomas C. Grimes' Tazewell, and a beautiful sorrel three year old colt, dam Miss Bethune, and sired by John Bascomb. Pennoyer, the property of Thomas Neal, sired by Sir Henry, dam Ariel; a handsome two year old colt by S. A. Pardee, sired by Tranby, dam the dam of Martin Jackson; a 3 year old Filly, by Seaborn Lawrence, sired by Barb, and dam a Florizel mare; a two year old bay Filly, by Andrew Bird, sired by Maxcy; a year old Colt by Mucklejohn, the property of Ellison Worthy, and another by Mr. Black, sired by Turk.

SWINE.

To Col. John Bonner, for the best Boar, Rip Van Winkle, a full blood Berkshire, a premium of $5.

To Mr. A. E. W. Bonner, for the celebrated Boar, Black John, a full Berkshire, 1st honor.

To Mr. James M. Hunt, for his Berkshire Boar, Bill, 2d honor.

To Mr. Jarard L. Turner, for his Berkshire Boar, Lafayette, 3d honor.

To Mr. James B. Ransome, for his Berkshire Boar, Toby, 4th honor.

To Col. John Bonner, for his Berkshire Sows, Nonesuch and Flower of Orange, a premium (divided) of $5.

To Col. Bonner, for Berkshire Sows, Black Rose and Kitty Clover—to Mr. Miles G. Harris, for his Berkshire Sow, Irone—to Dr. Alfriend, for his Berkshire Sow, Mary Black, the 1st honor.

To Col. Bonner, for his Berkshire Sow, Young Victoria, 2d honor.

To Capt. R. S. Hardwick, for his Berkshire Sow, Shakeress, and seven beautiful Pigs, 3d honor.

To Capt. Hardwick, for his Berkshire Sow, Sal, 4th honor.

Capt. H. exhibited several other Berkshire Sows of fine form. Various other young Sows were exhibited by different individuals of fine form and size, and so equal as to prevent an expression of opinion by the Club, as to their superiority. Among them were Col. Bonner's Berkshires, Sarah Fane, Myrtis, Betty, Mary, Peggy and Miss Ontario; Mr. Bonner's Berkshire, Jessie; two Berkshires by Mr. James M. Hunt, and two others by Mr. Bass, names not given; Mr. Bonner exhibited a beautiful young Sow, Crozett, a Berkshire and Neapolitan, and Col. Bonner a beautiful China, Anna White.

CATTLE AND SHEEP.

To Col. John Bonner, for his Bull, Sam Houston, 15-16ths Durham, a premium of $5.

To James B. Ransome, Esq., for his Durham Bull, 1st honor.

To Mr. Thomas C. Grimes, for his do. do., 2d honor.

To Capt. R. S. Hardwick, for his do. do., 3d honor.

To Mr. Grimes, for his Durham Cow, a premium of $5.

To Captain Hardwick, for his second best Cow, (and calf,) 1st honor.

To Col. Bonner, for the 3d best Durham Cow (and calf,) 2d honor.

To Capt. Hardwick, for best native stock, 3d honor.

To James B. Ransome, for his best year old Calf, one-fourth Durham, a premium of ——.

To Capt. Hardwick, for the best lot of Sheep, a Tup and two Ewes, of the South Down breed, was awarded an honor.

By order of the Executive Committee.

T. H. AUDAS, Sec'y.

DAIRY SALT.—Salt that is very white and fine in appearance is not unfrequently combined with other substances which injure its conservative powers; and hence that can only be relied upon which is prepared in such a way that a separation of these substances takes place previous to crystalization. In pure rock salt, nature has effected this separation perfectly; and where such can be obtained, and then ground fine, nothing as to the quality is left to be desired. The examinations made by our State geologists, prove, that next to this rock salt, (and vastly superior in strength and purity to the greater part of it,) is the coarse salt produced at the Onondaga Salines, by solar evaporation.—Thus Dr. Beck's analysis shows (see page 36, of the report for 1838,) that the salt made by solar evaporation at Geddes and Syracuse, contains 992 parts of pure chloride of sodium in 1000; while Turks Island and Liverpool fine salt gave from 984 to 988 parts in 1000. The fine salt put up as table salt, at Salina, exceeds the Liverpool in purity, and may be used in the dairy with perfect safety. But for a superior article, and one about which there can be no mistake, it is probable our farmers will find the salt made by evaporation, and then ground, the best butter salt that can be used; and we are confident if such salt was generally used in our dairies, the quality of their products would be most materially improved. Those who cannot obtain this salt, should use the best Liverpool fine they can procure, or purchase rock salt, clean, and grind it. This latter course, we understand, is taken by the Quakers at Fairfield, in Maine, the excellence of whose dairy products is admitted wherever they are known.

[*Cultivator.*

TOP-DRESSING.—We know of but few subjects of general discussion among farmers, in relation to which a greater diversity of opinion has been expressed, than in reference to the merits of top-dressing. Now it does, and indeed it ever has seemed to us, that the theory of top-dressing is correctly and philosophically based. And it was under this impression that we commenced, some years since, a course of experiments that has resulted thus far in a full, and as it seems to us, most conclusive corroboration of the verity of this belief. It is certainly the course which nature adopts in her operation, and in copying her example in this particular, there is obviously, we think, but little danger of going wrong.

In the autumn of 1840, we observed in the corner of one of our mowing fields, a spot which had become so thoroughly exhausted by long neglect as scarcely to produce enough to pay the expense of cutting. This place we at once determined to make the subject of an experiment, partly from our previous convictions of the utility of top-dressing, and partly from having recently witnessed the surprising effects produced by the droppings and stale of a few young cattle which had been permitted to feed upon some turnip tops that had been left at harvest in a contiguous field. Accordingly in the prosecution of this design we went to work and carted on to the worn-out and emasculated spot, nearly a dozen loads of old, well-rotted manure, being, as nearly as we could judge, from six to eight cords per statute acre. This was done the 20th of September. In the following spring the grass on the manured part of the field, took an early start, and at haying we had full a ton per acre, while the product of the other portions of the field which had not been manured in the fall, and which we had supposed were not sufficiently exhausted by cropping imperiously to demand it, did not exceed one-half that amount. Since then we have ever made it a standing rule to top-dress as much of our grass land in autumn as our circumstances will possibly admit.—*Maine Farmer.*

TERMS.

The "SOUTHERN CULTIVATOR" is published every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines or less for the first insertion and SEVENTY-FIVE CENTS per square for each continuance.

☞ POST MASTERS are authorized to receive and forward money free of postage.

☞ ALL COMMUNICATIONS MUST BE POST PAID.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., MARCH 15, 1843. No. 2.

RECENT AND EXTENSIVE MARLING IN SOUTH CAROLINA.

COLUMBIA, S. C., November 30, 1842.

DEAR SIR:—It affords me great pleasure to comply with your request, to furnish you with a statement of my marling operations during the first year, and the result of them so far as it has been ascertained.

I commenced in November last to marl my plantation at Silver Bluff, on Savannah river. There is no marl on the place. I procured it from Shell Bluff on the same river, and had to boat it twelve miles up the stream. It requires eleven prime hands to man the boat I use, and when the river is not too high they make two trips a week, loading and unloading themselves; They bring about 1100 bushels at a load. The marl is landed at a spot below high-water mark, and during the whole crop season two other hands and two carts are constantly engaged in hauling it to a place of security on the top of the bluff. At other times it is hauled directly from the landing to the fields. There are, however, thirteen hands and two mules lost to the crop.—My boat, which is a common pole boat, was built chiefly by my own people, and cost me about $300, including their labor. There have been incidental expenses to the amount of about $200 this year. During the year ending on the 8th of November, there were 85 trips made and about 93,000 bushels brought up. I think I can safely calculate on bringing up 100,000 bushels per annum hereafter, with the same force. I mention these facts that every one may form his own estimate of the cost of procuring marl under similar circumstances. My calculation is that it costs me about two cents a bushel delivered on my bluff. To one having marl on his own premises nearly the whole of this expense would be saved. I am enabled, by omitting to open new land, to haul out and spread this marl, without interfering with other plantation work, or lessening the number of acres planted per hand. In hauling out I have not been able to do as much as they do in Virginia. Mr. Ruffin, the author of the marling system, hauled 24 loads of 5¾ bushels with each cart per day a distance of 847 yards; I have done but little over half as well. I use mules, however, and the land being level, carried 6¼ bushels at a load. I found the mules could not stand trotting back with the empty cart. The marl weighs about 105 lbs. per bushel. My land was laid off in squares, so many to an acre, and a load dropped in each square. It was spread by hand; each negro taking his square, and carrying his marl on a board or in a small tray. A prime fellow can spread an acre in a day. But it is a hard task, and counting the gang round I have not averaged over half an acre for each worker. The marl spreads best when damp. It will then yield to the hand, and lumps are in general easily crushed.

Shell Bluff is a bold cliff on Savannah river, over 200 feet high, and, in some places, more than 100 feet perpendicular. Professor Vanuxem, who examined it some years ago, (see Farmers' Register, vol. vii. p. 70, and also vol. x. p. 487,) discovered fourteen varieties of marl, varying in quality from 37.2 to 93.4 per cent. of carbonate of lime. In using the marl I have excluded the inferior as much as possible, and have not found the very best in any great quantity.—I tested the quantity of carbonate of lime in one specimen taken at random from each boat load brought up this summer, and found the average of thirty-four loads to be 62.8 per cent., varying from 51 to 77. In every specimen there was a small proportion of oxide of iron, and clay and sand, usually in about equal quantities. There were, no doubt, other component parts which I did not ascertain; but I satisfied myself that there was neither gypsum nor magnesia. The marl presents various appearances, being in color white, brown, olive, yellow and violet, and in consistence from sand to soft stone. Some of it appears to be a concretion of shells from a size scarcely visible to the naked eye to an inch in diameter. There is no hard limestone, and it is doubtful whether any of the marl here will make lime, though it is an excellent cement. Much of that which I have used has been cut from the face of the cliff with pick-axes. It falls down sometimes in fine grains, sometimes in masses. At every handling it breaks up finer, and exposure to the air assists disintegration. I do not burn or pound it. Where it was spread last winter, an observer would readily discover it, and lumps as large as an egg, and occasionally much larger, are to be seen. A mere passer by, however, would not notice that the land had been marled. At every working it is more and more mixed with the soil. But I imagine it will be several years before it is completely combined with it, and until then the full effect of this marl cannot be known. A difference was apparent in this crop between the effects of that spread early in February and that spread in the latter part of April.

By the 22d of April last, I had marled 175 acres at the rate of 200 bushels to the acre. Of these I planted 50 acres in corn on the 17th of March, 50 acres in cotton on the 10th April, and 75 acres in cotton on the 22d April. These three cuts are in the same field, and adjoining, being separated only by turn-rows, yet the soils vary considerably. In the corn, I laid off four separate acres along the turn-row, as nearly equal in quality as possible. The one supposed to be the best was left without marl. The others were marled with one, two and three hundred bushels respectively. It was all of the same boat load, and contained 54 per cent. of carbonate of lime. This land has been in cultivation more than one hundred years. I have planted it myself eleven of the last twelve years, and sowed it in oats the other year. I have given it three light coats of manure, the last in 1839. It is a light, gray, sandy soil, of which the following was the analysis before marling, viz:

Water lost at 300 degrees	2	per cent.
Vegetable matter	3	"
Silica	80	"
Alumina	11	"
Oxide of iron	2	"
Loss	2	"
	100	

This cut was in cotton last year, and my expectation was, that with common seasons it would produce twelve bushels of corn per acre. And had I not kept the unmarled acre as a test, I should have set down all over that quantity to the credit of the marl. The corn came up badly, and suffered by the birds. The four experimental acres were cultivated precisely as the rest of the cut, and were distinguished only by the posts which marked the corners of each acre.—From the first, however, the marled corn exhibited a different appearance. It was stouter and of a much deeper color. As the season advanced, the difference became greater. The marled corn was as dark a green as swamp corn usually is. The fodder was pulled on the 3d of August, and after hanging two days and a half on the stalk in dry and rather windy weather, weighed as follows:

		Increase.	Per cent.
Unmarled acre	250 lbs.		
Marled at 100 bushels	285 "	35 lbs.	14
" " 200	" 314 "	64 "	25.6
" " 300	" 261 "	11 "	4.4

The corn was gathered on the 24th of October, being thoroughly dry and having shrunk as much as it would in the field. There appeared to be little or no difference in point of soundness. It was shucked clean and measured in a barrel. The unmarled corn shelled out two quarts less to the barrel than the marled. The following was the result:

		Increase.	Per cent.
Unmarled acre	17 bush.		
Marled, at 100 bush.	21 "	4	23.5
" " 200	" 21 "	4	23.5
" " 300	" 18½ "	1½	8.8

From this it would appear that 100 bushels of marl was as efficacious as 200, and perhaps in such land as this such may be the fact. It appears also probable that 300 bushels to the acre is too much. I ought however to state, that this last acre had a slight sink in the centre, and that the slopes around it are much thinner than the average land. These constitute about one-fifth of the acre, and were evidently injured by the marl. It was a bad selection for the heaviest marling; but at the time it was made I did not suppose, judging by the rates at which they marled in Virginia, that 300 bushels would injure any land. My fear now is that 200 bushels may prove too much for soil like this; and I have accordingly determined to put only 150 bushels on the acre hereafter, until I see its further effects. This has been a remarkable productive season for corn. I think the unmarled acre in this cut made at least five bushels more than it would have done of an average year. I presume the marled acres have done so likewise. But whether it would be fair to attribute any of the four bushels increased to the peculiarity of the season operating on the marl, I am wholly unable to decide. Supposing the increase from the season to be the same on the marled and unmarled land, and deducting five bushels from the produce of each acre, there will be 33⅓ per cent. in favor of the ten best marled acres. This, however, is all conjecture. The average per acre of this whole cut was eighteen bushels. The measurement of all but the experimental acres was made however by wagon loads, according to the usual plantation estimate, in which there is a liberal allowance for shrinking, &c. Had the whole been measured in the same manner as the experimental acres were, the produce would have appeared greater. I have had this cut planted in corn once before, but having been absent the whole year, no account of it was preserved, and I do not know what it produced.

I selected also and laid off separately four acres of cotton along the turn-row of the seventy-five acre cut of cotton. At the time I thought them nearly equal in quality, and the one supposed to be the best of these was left unmarled, and 1, 2 and 300 bushels of marl spread upon

the other three. It turned out however that the acre with 100 bushels was inferior to the average of the cut, while the other two were far superior. I was deceived by the stalks grown the year before. The two first named acres being somewhat rolling, and the year a wet one, they produced as good cotton as the other two which were flat. The unmarled acre was not much if any superior to the one marled with 300 bushels, save that there was a spot where fodder stacks had stood in 1838–9, which produced nearly double the cotton of any other spot of the same size in either acre, and added probably 30 lbs. to the amount gathered from that acre. The marl on these acres contained, like that on the corn cut, an average of 54 per cent. of carbonate of lime. This land is of the kind commonly known as *mulatto* soil, and was cleared at least as early as the corn cut. It was certainly planted by the Indians in 1740. The following was the analysis of it before marling, for which, as well as for the analysis of the corn cut, I am indebted to the kindness of Prof. Ellet:

Water at 300 degrees	3
Vegetable matter	4.5
Silica	74
Alumina	14.5
Oxide of iron	4

This cut was not planted until the 22d April, because it could not be marled before. A dry spell occurring immediately after, at the end of two weeks very little cotton had come up except in the marled acre, in which there was about half a stand. My overseer becoming alarmed in my absence, replanted the whole, and threw out the whole seed wherever it had not come up. This was done on the 6th May, so that the crop of this cut dates from that period, which is at least a month later than I should have preferred. For my experience is that early cotton, like early corn, is almost always the best. I consider the two weeks start which one half the unmarled acre obtained in this instance as of considerable consequence to it. These early stalks could be distinguished until the bolls began to open. The difference between the marled and unmarled cotton was as obvious as it was in the corn. The leaf too appeared broader and the stalk stouter from the first. The following was the production of these four acres. I state the production of all, though that of the 1 and 200 bushels acres ought not to be compared with that of the other two, on account of the relative inferiority of the soil.

The unmarled acre	1111	lbs.	in the	seed.
Marled do. at 100 bush.	846	"		"
" " 200 "	1003	"		"
" " 300 "	1318	"		"

The difference between the unmarled acre and that with 300 bushels of marl, was 17.7 per cent in favor of the latter. It would have been greater perhaps any other year than this, which has been almost as favorable for cotton as corn.—The average production of the whole 75 acres was 966 lbs. per acre. I have had this cut in cotton ten of the last twelve years; in corn one, and in oats one, and the following is a statement of its production of cotton for six of the ten years; that of the other years not having been preserved.

1833 av'ge pr acre in seed	731	lbs	manured	lightly
1834 " " "	784	"		
1835 " " "	951	"	manured	lightly
1836 " " "	451	"		
1840 " " "	497	"		
1841 " " "	500	"	manured.	
1842 " " "	966	"	marled.	

The other 50 acre cut of marled land planted in cotton on the 10th April. It came up in good time and was a fine stand. This is also a light gray soil, with less clay than the mulatto land, and less sand than the corn cut. It is probably as old as either, and has been cultivated in much the same way. Although planted ten days later than some other fields, and after all of them except the 75 acre cut, it soon appeared to be the oldest cotton, and certainly matured the earliest of any. Immediately after the cold weather, about the first of August, the rust commenced in it, and by the 20th of that month it had the appearance of a field after frost. Forms, small bolls, and even the leaves dropped. Most persons who saw it thought it had been cut off one half. I think myself it suffered to the extent of one-fourth at least. But I have made on this cut this year 840 lbs. of seed cotton, which is nearly 50 per cent. more than I ever had made on it before. The following is the average of its production for four other years.

1833 av'ge pr acre in seed	596	lbs	manured.	
1834 " " "	435	"		
1840 " " "	363	"		
1841 " " "	366	"	manured	lightly
1482 " " "	840	"	marled.	

I think the injury from the rust nearly or quite equal to the benefit derived from the favorable season. And that the increase from the marl was greater on this cut than on any other, because the earliest marled and most seasonably planted. The rust here was more injurious than in any other field, and I might have attributed it to the marl, but that the 75 acre cut, also marled, suffered least of all. I am inclined to think that the most advanced cotton was most affected, and the youngest least, and that marl had no influence one way or the other. It is worthy of remark, that while all my other cotton suffered from lice and the worm both, neither made their appearance on the marled land.

I have troubled you with this lengthy detail of my operations, because this being the first serious experiment with marl in South Carolina, (that I know of,) it may be interesting to those who have this earth within their reach, to know the particulars. From the facts I have stated, each one can form his opinion on nearly as good data as I can my own. I can only add that my expectations for the first year have been fully answered. I did not calculate on any of those magical results which agricultural experimenters so often look for, and so seldom realize to the full extent. I regard an increase of 20 per cent. as a very handsome return, and if it only does as well another year, I shall at all events be repaid for my labor, even if the beneficial effect of the marl ceases then. But the experience of all who have used it is, that it continues to improve the soil every year, until thoroughly disintegrated and combined with it; and that with proper culture it never declines from its maximum. Under these circumstances, and with these hopes, I shall continue myself to prosecute the business vigorously during the summer. I have hauled marl over 100 acres, and have now at my landing enough to cover 300 acres more. My great regret is that I did not engage in the business sooner. I have long known Shell Bluff, and for some years had heard of Mr. Ruffin's successful introduction of marl into the culture of Virginia. But I had not read his "Essay on Calcareous Manures," nor examined Shell Bluff, until the summer of 1841. The idea of obtaining marl from that spot was first suggested to me by my friend Mr. Dickenson, of Georgia; and after a careful perusal of Mr. Ruffin's Essay, and an analysis of marls there, I determined to try the experiment. I have, during the course of it, received much encouraging and valuable practical information from Mr. Ruffin himself, to whom, in common with all other beneficiaries of this inestimable treasure, I owe a debt of gratitude which cannot be easily cancelled.

I am, my dear sir, with great regard and esteem, your obedient servant,

J. H. Hammond.

Hon. Whitemarsh B. Seabrook,
President of State Agricultural Society.

[*Farmers' Register.*

To Destroy Ants.—Mix an ounce of powpered arsenic with a quart of water, boil it half an hour with some sugar, and place the syrup in small shallow vessels, oyster shells will do, in places infested by them. The sweetness attracts them, and the consequences are speedily fatal.

☞Salt is said to be good for hogs. It will sometimes restore their appetites when they have refused to eat. A little charcoal is good at times.

BOMMER'S METHOD OF MAKING MANURE.

We invite attention to the annexed Report of Dr. Beck, on Bommer's Method of preparing Manure. From a careful examination of the specifications and directions furnished us by Mr. Bommer, as well as from a personal examination of the process, from the forming of the heap to its opening, we are convinced that the method must prove valuable, and the manure so prepared of the best quality. There are many farms on which immense quantities of coarse grass, thistles, sedge, flags and other weeds, are annually grown, of which no use can be profitably made; all these, and with them the large piles of straw which are heaped round many barns to cause them to decay, may, by this method, be expeditiously and cheaply converted into the best of manure—the cost of the materials which the farmer will have to purchase being only from fifteen to twenty cents per cord, and the labor only such as is necessary to form a compost heap of any kind.

Report on Bommer's Process for Making Vegetable Manure, by Fermentation.

At the request of Mr. Bommer, the undersigned were present on the 14th of September, at the preparation of the materials used by him for making the above manure. As Mr. Bommer's process is patented, it will of course not be expected that the committee can go into details farther than what he himself makes public.—They have, however, no hesitation in stating that the materials mentioned in his specification were all used; that the experiment was in every respect fairly made; and that the whole is evidently conducted on the most approved chemical principles.

Two heaps were prepared; the first made of dry materials, principally straw of various grains, and probably weighing about 1,000 lbs.; the second was composed of ligneous vegetables, dry and green—such as cornstalks, potato stems, thistles and various other weeds. This weighed probably about 450 lbs. and was propped against the first heap.

The following table was kept at the request of the committee. It exhibits the degree of heat developed during the process of fermentation, ascertained daily by immersing the bulb of a thermometer in the centre of each heap.

The fermentation was discontinued September 28, when the heaps were opened for exhibition. The committee examined them on the 8th of October, and are quite satisfied that the result is a satisfactory one. The heap formed of 1000 lbs. dry straw was found to contain by measurement 225 solid feet, or one cord and three quarters, estimated to weigh 4,000 lbs. The material furnished must prove a valuable manure; and the more so, as it employs many articles now worthless or deleterious. In all matters of this nature, experience is of course worth more than mere theory; but it will be a matter of great disappointment if a process combining, as this does, an application of the most correct chemical principles, with the employment of the most efficient agents, does not in due time become a favorite with the farmer.

T. R. Beck, Ch'n.

Mr. Bommer states in his prospectus that the merit of his method essentially consists in the four following important points:

1. In being able to reduce in a short time all kinds of straw and ligneous weeds to a rich, unctious and durable manure, sueh as wheat straw, barley, rye, buckwheat and other black grains; stalks of Indian corn, rice and other plants; dried or green potatoe tops, leaves, stalks and roots of all kinds of plants; green or dried reeds, green rushes, sea weeds, sea rushes, heather broom stubble, in fact every thing belonging to the vegetable kingdom, and a great many other things lying about farms which are often allowed to go to waste. Even the ground itself may be converted into the best manure or compost.

2. In the combination or alliance of fecundating substances, the use of which when separated would not and could not produce the desired effect.

3. In the produetion of a very considerable quantity of factitious water, which when combined with other ingredients, forming lees, furnishes the farmer with a fertilizing liquid, the commixture of which in either vegetable or mineral substances, gives a manure of the richest kind.

4. In the production of a quantity of nitrate of lime and caustic potash; of ammonia and saltpetre—four substances which modern chemistry has found to contain the most fecundating properties possible.—*Cultivator.*

VALUE OF PLASTER.

The subjoined extract from a communieation, which appeared in the last Massachusetts Ploughman, speaks in just terms of the value of Plaster as a manure, and as the experience of the writer accords in results with our own, we give it insertion.—*American Farmer.*

"In passing through Pennsylvania, which I frequently did, I heard much said of the benefits of Plaster of Paris; a great many of the farmers, I was told, would come fifty miles to Philadelphia, in the time of last war, and give twenty dollars per ton for Plaster, and let their manure go down stream rather than to be at the trouble to cart it on their lands. I do not speak of this as approving of it, for I think every farmer ought to make as much manure as possible. I was told the way the Dutch farmers used it there was to sow clover and put one or two bushels of plaster to the acre and plough in the crop and sow wheat. I was informed in Baltimore, that a great deal of land on the eastern shore of Maryland, which had been worn out by raising tobacco and corn, had been reclaimed by the u % of plaster. Having got my ideas so raised, the first thing I did after I got a piece of land was to try it, and in three weeks after I applied it. On examination I thought as the Queen of Sheba did when she visited King Solomon, "the half had not been told me;" it was applied to a piece of loamy soil which had recently been laid down and one crop of hay cut from it, say half a ton to the acre. On the first examination after the plaster was applied, there was three times as much as when there was none. A part of this piece of land has been kept for a pasture ever since and never has been ploughed, and I think I can safely say there is not another piece of land in town that produces more feed. It has frequently been plastered since, and occasionally ashes have been applied as a top-dressing. The manure the cattle have dropped has every year been gathered up and put into the manure heap, so that it has no other dressing but plaster and ashes except the urine from the cattle.

Well, being so well pleased with the result of this small experiment, I tried it on a larger scale on my farm with as favorable results. On many places three bushels of plaster would make more grass grow than twenty loads of manure. I fenced off nine acres that had been fed very close by sheep for a number of years; this was the highest part where the sheep had generally lain through the nights; this was plastered at the rate of three bushels to the acre; the next season it pastured from May to September twelve cows, at the rate of three-fourths of an acre to a cow, and they had as much feed as they could eat, and on a great part of it we could have mowed a good crop in hay time.

From this time people began to use plaster considerably, and found a very great benefit from it; many of the old pastures which were covered over with moss, were converted into beautiful fields of clover; but strange to tell, just on the eve when our pastures began to be clothed with a beautiful verdue, and our farms bid fair to produce double what they were wont to do, there was a story got up by some gossip, which spread like wild-fire, that this plaster which had produced such wonderful effects was not what it was cracked up to be; that it would ruin the land if we continued to use it; if it did not happen in our day it would in our children's; that it would run our land all out and our children would become beggars. Now as this story, like other bugbears, has had its day, I find they are beginning very moderately to use it again. I hope that no farmer will rest satisfied until he has given it a fair trial; the expense is very trifling; at present I believe it can be bought for two dollars per ton; that it won't cost more than twenty-five cents per bushel, three bushels per acre, which is a great plenty; that the expense of manuring an acre is seventy-five cents, which will pay but a small part of the expense of carting on any other kind of manure if you had it given to you. Wherever the plaster will do any good it ought to be applied; and the only way I know of is to try it. On some land it will do no good I am confident. I had a large piece of plain on my farm, on which I could not see the least benefit from it; this was a deep black loam and rather moist; as soon as I went from this plain, over all the hills it worked wonders.

Yours, with respect,

Benj. Wheeler.

Farmingham, January 2, 1843.

DEEP AND SHALLOW PLOUGHING.

No question in agriculture, perhaps, has afforded a source for more conflicting opinions amongst planters and farmers than the necessary depth of ploughing. This fact itself presumes that the question is connected with things that are mysterious; or that general principles have been formed by some, under peculiar circumstances; and by others, under different circumstances; without respect to depth of soil or qualities of soil and subsoil, the preparation by the plough for cultivation, or its use in the act of cultivation. The object therefore of this article is to arrive at those general principles which will apply to cases under all circumstances, so that rules may be varied accordingly. The science of agriculture in this respect is like the science of medicine. That physician who undertakes to cure all diseases with one medicine may be set down as a quack; and he that does not use means according to the circumstances of the case in agriculture, is no less deficient in that science.

In order to investigate the subject fully, let us suppose different cases under their different circumstances, familiar to all intelligent planters, and from those facts deduce our arguments.

1st. Every planter who has any experience must know, that to a free soil, easy of cultivation, and to give free cultivation to the roots of most plants cultivated, there must be a suitable composition of sand and clay, in order that the soil may be sufficiently porous, and yet not too much so. If, therefore, the native soil is too sandy, and a clay subsoil is in reach of the plow, the advantage of deep ploughing to effect a mixture will be seen at once, so far as that object is concerned. Another fact known by agricultural chemists, that while silex is an essential food for most plants, potash is also equally essential as a food for all corn or grain plants cultivated. Professor Liebig has proven that all clays contain more or less potash, and all know that sand is chiefly silex. Hence the mixture must increase its fertility, as well as effect a more perfect consistency.

A 2d case. Let us suppose a soil of proper consistency and of sufficient depth to afford the moisture and play for the roots of the plants to be cultivated. To plough up extraneous matter not so rich in alkaline or earthy manures, and destitute of vegetable matter, must necessarily impede the growth of its plants. Out of the latter case we will suppose a

3d. That this virgin surface soil, (say 3 or 4 inches deep,) has been cultivated until exhausted of its potash, magnesia or other earthy manures, or either of them, as well as its vegetable matter. We may fairly reason, that if the subsoil furnished the earthy manures to the surface, there remains further supplies, and by adding vegetable or animal manures, and turning up the subsoil to the snows and freezes, as well as to the sun, to prepare it for action upon the roots of plants, restoration must be completed. And if the subsoil contained the necessary properties of alkaline or earthy manures, it is much easier to supply the defect by the plough, than the purchase of lime, plaster, or to haul from marl beds, except very near at hand. And upon this principle may be accounted how lands, originally rich, will regain their fertility by rest.—They promote a growth, the roots of which descend and gather from the subsoil its alkaline or earthy manures, the leaves and stalks collect carbon and ammonia from the atmosphere, and all returned to the surface restores a new soil.—If this can be effected by the plough and a native or cultivated growth in a few years, or by the addition of vegetable or animal manures mingled with the subsoil, why leave it (to the 2d generation) to restore itself?

A 4th case. Suppose a soil six inches deep, has never been ploughed more than three inches in depth, and that those three inches are now exhausted. It is evident that it is only necessary to turn up the lower coat and give it time for the action of the atmosphere, in order to restore it to the former production. It may be said, (if the land is rolling,) that this advantage is precluded by the rains washing off the first three inches.—In flat and level lands, however, this is not the case. Out of this arises another question or case.

The 5th. Suppose a soil six or even twelve inches deep, in its fresh state. Should it be ploughed as deep as the soil extends? Answer—Experienced planters know that the roots of corn and cotton, if not small grain, will run a foot deep, if the lands are broken up that depth, especially if ploughed once as deep after planting. It is also known that soil, however fertile, that has remained excluded from the atmosphere too deep, will not bring its nutritious qualities to bear on most plants cultivated. It therefore follows—that if the roots of plants have twelve inches of soil to feed and branch in, they must have more food, more room, and more moisture, and therefore a proportional increase in production.

A 6th case. Suppose a Spanish oak ridge, with a growth of green brier and shrubs, indicative of poverty, with not over an inch of vegetable soil upon it. What depth should it be plowed? To plough such a thin skirt of soil six to eight inches under, the plants would perish be

fore their roots could reach the scanty supply of food, and at once add death to poverty. By shallow ploughing, and wet seasons, a little may be made, but it would prove lost labor to plough in the best way. If level, it may however afford a good foundation to locate a soil, by hauling it from steep and rich neighboring hills; and perhaps an inch of the native earth might aid in the composition. If analyzed, it might possess some one or two properties of earthy manures, and if that was known, and the others added, fertilizing would be less expensive and more certain.

A 7th case. Suppose a rich alluvial soil is deposited upon a sand bar, and that this stratum of soil was five or six inches deep. Would it be safe to plough through it? By ploughing thro', it would give the roots an unprofitable access to the barren sand, open the way for the rich soil to sink, and effect an unprofitable mixture, and most of alluvial soils are of a good composition. If not, it might prove safer to add to than to break through the soil.

An 8th case may be supposed by reversing the 7th. That is, suppose a sand bar of 6 or 12 inches deep covers a rich black or blue clay or mud. Experiments have tested that by ploughing up the clay the most fertile and productive soils have been made in bottom lands, especially where the stratum of clay was the original soil.

Many other cases might be supposed connected with other peculiar circumstances. Enough however is written to establish this truth—that circumstances must vary cases even in different parts sometimes of the same field. And to contend for deep ploughing indiscriminately, would be, as said, like a quack using one medicine or course of practice to cure all diseases. The above remarks, however, are only intended to apply in the preparation of lands for cultivation, and not to the ploughing of crops, when planted. As circumstances will there be again different, that part of our subject will be reserved for a future article.

We have shown that the depth of ploughing in fallow lands must be regulated by the different circumstances of soil, subsoil, &c.—The same circumstances must not only have their bearing in cultivation, but others necessarily arise, which must still change the depth in ploughing. The objects of fallow ploughing were to improve the soil by admixture with the subsoil, and exposure to the winter or spring atmosphere, as well as to pulverize it. The last object of the three is still to be kept in view, while the other two have accomplished their ends. Science has taught us and facts bear testimony, that exposure of subsoil to a winter atmosphere collects carbon and nitrogen, and to a summer atmosphere causes evaporation. Another item in fallowing is to turn the grass and weed seed under deep enough to prevent their coming up, which, if avoidable, should not be raised on the surface again. The chief objects in cultivation are therefore to pulverize, to kill grass or weeds, and according to the nature of the plant cultivated, to hill up. If the soil is sufficiently porous, that circumstance should be kept in view. If too porous, that should have its bearing. Let us suppose, in the first place, that the fallow ploughing has turned up a turf or sod four or six inches deep. It will follow of course, that in the first ploughing for cultivation this turf must be broken and crumbled its full depth. And to carry out the principle laid down, the plough should be constructed so to work as not to reverse the surface again, which may be effected by a long narrow pointed shovel. This being done as a first ploughing after planting, a question now arises—is the object of pulverizing sufficiently effected, so as to render any further labor unnecessary upon that score? In sandy or porous lands, there can be no doubt upon this question. But even in stiff clay lands, experimental facts can be adduced, made in different seasons, to prove that two ploughings 4 inches deep, will secure moisture and porosity sufficiently for the roots of corn or cotton to play as deep as ploughed that year. In stiff lands, heavy rains may cause a crust one or two inches on the surface. Now as all experienced planters know that lands may be easily made too porous, and that a certain degree of solidity is necessary to protect the roots of plants from a cold atmosphere, and the burning rays of the summer's sun; when the true object is effected, an injury will be sustained, if carried too far; or to say the least, the labor is lost. Tow-thirds of our planters, however, will urge that clay lands will (to use a common phrase,) cake after every heavy rain. But this error arises from the fact that the first ploughings have not been over or very little over two inches deep; for if those who are thus deceived would throw off the loose earth around a furrow, and measure the solid part perpendicular, they would discover a mistake in the supposed depth. And it is certain that old stiff lands, not ploughed over two inches deep, will consolidate as deep after every heavy rain. If these premises are sustained, the only remaining object as far as pulverizing is to effect any good, is to stir the surface crust, if formed. But here, at least, one half of our planters will say, the roots of corn and cotton ought to be cut to make a better production.—And it is not hard to account for this corn and cotton destroying mistake. The first ploughings as the earth was hard and the ploughs unfitted for the purpose, have only effected a kind of scarification of a deep soil; the roots are of course confined on the surface, and if ploughed at all must be cut any way; it is therefore better to plough deep now than never, even for the wounded roots to have depth of soil to branch in, than to leave them uncut, to perish on the surface, for want of soil and moisture. It is argued sometimes that roots should be cut upon the principle of pruning trees, vines, &c. But if we argue upon this principle of nature, it goes to condemn the practice. We cut the top that the roots may be better enabled to sustain the remaining top. And to test the principle, let a young plant of corn be drawn up in a wet season and transplanted, and in two cases out of three an ear will never be produced of any size; yet, let the frost or an animal cut down the top when young, and the ear will be equally good. Further, if a young tree is raised and transplanted, the more root left the more certain and rapid the growth of the tree. If any, however, still doubt upon this question, let them make a fair experiment by ploughing from four to six inches deep, according to the soil, &c. the two first workings; and after one or two inches deep, taking care not to cut the roots by the hoe in hilling, selecting two acres with equal advantages otherwise, cutting the roots of one, and avoiding the other as far as practicable. And results must vary from experiments made by others, or proof will be afforded to settle the question.

If this question be established, the only remaining object in the next two ploughings (making 3 in the cultivation,) should be directed upon the plan calculated to pulverize the crust, and kill the grass most speedily. And for this, one eagle plough is worth two, (if not three,) of the widest and best shovels. What we call the eagle plough about Monticello, is not what is called the scraper, or the clumsy imitations of the eagle plough used in many sections of the State; but a plough which finishes a middle of 3½ feet, (it of equal distance) by one furrow; or a 5 feet middle by two furrows; without running over one, or one and a half inch, in depth.

This plough, if skilfully made, set and managed, will kill grass more effectually than a shovel; leave the middles in a better state for the roots to have play upon all the soil; the middles less liable to wash; by running two furrows in a middle, hill up corn or cotton, so as to cover grass in the drill; and yet not heavier in draft than a wide shovel.

Much more might be written upon the many important circumstances and principles, connected with this subject; but enough for the present object of this article; which is not only to afford the advantage of the experience of the writer to young planters, but to draw out the experience and discoveries of others, which may go to confirm true principles, and to correct any errors advanced; for the grand object of agricultural societies and papers, is or should be, to collect and treasure up the wisdom of the many, and to encourage all to further discoveries.

MONTICELLO.
Temperance Advocate.

HOW TO MAKE A LARGE COTTON CROP.

Extract from an article published in the Albany Cultivator.

This improvement, when it shall have attained its highest state of perfection, contemplates the "*system of rotation*" in planting, under which the land designed for cotton lies the previous year in the state of fallow, which is found by experience most favorable to the growth and fruitfulness of the plant. I commence the preparatory operations for planting about the 1st of March, by spreading upon the land *broadcast* two to three hundred bushels of manure per acre—light stock yard and stable compost. I then run off the land in rows of three feet with a scooter plow, opening a good furrow some three to four inches deep; this done, I take a large sized shovel plow and cross the scooter furrows by rows, running at right angles, of five feet wide. I am now prepared to commence manuring in the hill, having first ascertained that I have 2940 hills on each acre, which will require, by giving each hill a half gallon of manure—same kind of compost—184 bushels nearly, which I haul on the land in a cart, first graduated to a certain number of bushels, and with spades likewise prepared for the purpose, I deposit the requisite quantity of manure in each hill. By this means, which in practice will be found simple and expeditious enough, I give four to five hundred bushels of manure to each acre—*an infallible insurance* for 5000 lbs. of a superior staple per acre. As the manure is placed in the hill by rows, the wide way, a short distance in advance, a *good plow hand* follows with a turn plow, which should run into the soil from *six to eight inches deep* at least, and turn well, with which four furrows are thrown together on each row: thus fixing the half gallon of manure in each hill, entirely within the *region of constant moisture*.—This gives me a fine, large bed, and well broke, to lie until at or about the first of April, when the cotton seed should be planted. This is done by first opening the bed as shallow as possible, with some instrument such as that described by M. W. Philips, Esq. in the March number of the 9th vol. of the Cultivator. This I prefer to any other instrument of the kind I have ever yet seen, since its depth of furrow may be graduated to a positive certainty so as to avoid disturbing the manure in the hill; it should not be opened out deeper than one inch. The bed thus opened, and the seed previously rolled in leeched ashes or sand, which answer very well, though I prefer a compound of two parts of ashes to one of common salt made moist with water; the seed, well rolled in this, are carefully dropped over the manure. Eight or ten seed in a place will answer to secure a stand. There will be no difficulty in dropping the seed over the manure in the hill, when it is recollected and observed that upon the unbroken space of some two feet between each row, the scooter furrows will be found an unerring guide to the manure in the bed at distances of three feet. The seed thus dropped I prefer to have covered with a hoe, *lightly and carefully;* bearing in mind this golden truth, that "a crop well planted is half made."—Immediately after planting, the middles or unbroken balks should be plowed out. The crop of cotton thus planted, which should not exceed *three to four acres* to the hand, may be performed in good time and well done. In a few days, say nine to twelve, the cotton will be up, presenting a most healthy and thrifty appearance. The next operation to be performed, as early as possibly convenient, is to plough out the middles *well*, the wide way, with a good shovel plough, having first run around the young plant with a scooter plough. The hoe hands follow and thin the cotton down to two stalks, giving it a small quantity of soil. This operation *well done*, the

plant is at once placed beyond all danger, since its tap-root will now have taken such hold upon the manure below as to enable the plant to outstrip either grass or weeds, having yet to spring up.

Under this treatment, the *time-consuming* and worse than useless operations of *bar-shearing, scraping* and *chopping out* are saved, as much to the benefit of the tender plant, as to the interest and economy of the planter, in despatching the *hurry and push* at this stage of the crop; and at the conclusion of this first working, I have my cotton growing off and doing well. I have now no further use for a plough in its subsequent culture, but use the *sweep*—a kind of horse-hoe—I call it a sweep in the absence of a more appropriate name.

[Here follows a wood cut representation of the sweep, a kind of plough used by some planters at the South. The one here recommended is made by welding two narrow wings over the point of a scooter or bull tongue, inclining backwards, with the ends of the wings two feet apart. It is so fixed upon the stock (that of a common shovel plough) that it will not enter the ground deeper than one inch, if so deep.]

The great and singular advantages of the sweep over all instruments of the plough, harrow or hoe kind that I have ever used, are these —that it will *kill* a greater quantity of grass and weeds in a given time, and *do less injury to the surface roots* of the plant, *so essential* to its *progressive* prosperity. The hoe-hands following this instrument, thin the cotton to a stand, *one stalk* in a place, and draw up a small quantity of soil to the standing plant. The entire subsequent culture is performed with the sweep and hoe, which should simply scrape and pulverize the surface, so as to kill any grass and weeds that may appear, and allow a *free circulation* of atmospheric air to the fibrous roots of the fruiting stalk, requiring at this *critical period* all the aid and nourishment that culture, soil and atmosphere can afford. By the first of July my cotton stands from five to nine feet high, and I have it topped by the 10th at farthest, after which I run the sweep once through it, and the hoe if necessary, to remove any grass that may have sprung up immediately above the stalk. After this, and by this time frequently in places the cotton will be so much interlocked, and the ground so shaded, as to keep down all other vegetation—yet it may be found necessary again to chop about in places with the hoe, when the cotton may not have locked so early. This should be invariably attended to. This brings us again to the season of harvesting the staple.

Let no planter prejudge and reject this system, upon the score of simplicity, supposing the process too simple to accomplish the object proposed; first, act wisely, make the experiment and try it. Strictly follow this plain and simple process, and if the land does not reward your painstaking, with *five or six fold the quantity per acre*, of a *superior staple*, than has at any previous season been taken from it, in its natural state, I will present the experimenter with *one bushel* of my *improved seed*, with which to perfect the experiment. At another time I propose devoting a paragraph to the importance of *selecting and improving* cotton seed.

It will be observed that manuring constitutes a large item in this system of improvement, a source of revenue too much underrated by planters, and consequently too much neglected, because the subject requires a little extra attention —which attention is so essential to the prosperity and well-doing of a farm. Nor, gentlemen, have I seen any thing better said, or more true, than I find in the sentiment, under the head of "*a few queries*," in the last December Cultivator, where you remark to the planter and farmer: "In your manures is your *gold mine*, more valuable than any of the Carolina ones, and you should be anxious to increase them accordingly." But I hear some planters say—"it is impossible to produce so much manure"—this is, however the result of inexperience, and the want of *determination*. I am entirely convinced, from my experience in making manure, that it is not only practicable, but a perfectly easy task to prepare, upon every plantation in the cotton region, great or small, 1500 *bushels* of an excellent article of compost, per annum, to the hand—at a cost of less than two cents per bushel—by the assistance of the stock of horses, cows and hogs, upon properly arranged lots. This is done by having the lots well littered, by throwing in pine straw, in large quantities and frequently, or oak leaves, where the pine straw is not to be had, with cotton and corn-stalks, &c., and occasionally haul and scatter upon the litter a few loads of muck or marl, one or both of which may be found on or near every farm in the country; upon these lots, pen and feed your stock every night. The manure thus prepared, should be collected in pens or pits, three or four times during the year, after heavy falls of rain, and the lots replenished with pine straw, &c.—by this means a very large amount of manure is collected during the season, and that too, at an inappreciable cost.—Again, we have another difficulty; there are but few persons who believe that pine straw can be converted into manure; for the benefit and information of such, who may read this, permit me to quote a single sentence from Liebeg's celebrated work upon Agricultural chemistry.—"The bark and foliage of oaks contains from 6 to 9 per cent of potash. The needles of firs and pines *eight* per cent." But it is not on account of the potash exclusively, that I prefer pine straw, to all other vegetable matter, in the preparation of manure—since it possesses another invaluable quality above all others, in absorbing the juices of the manure, which are thus saved from evaporation, and readily applied to the land. I doubt not but a single year's experience will convince every intelligent planter of the innumerable advantages of this improvement, and its perfect adaption to the culture of cotton and other crops.

I will now close this number by a very few remarks upon the character and quality of the soil upon which my experiments have been conducted. It is a high ridge land, readily recognized, and its quality distinctly understood, in our southern country, under the name of "*forked-leaf, black-jack, pine-barren*," a deep, porous, sandy, superstratum, lying under a tolerable good clay, at a distance of two to three feet below the surface. A true picture of nature, and naturally poor enough. This land, under the treatment above detailed, grew my cotton, from which I have gathered a greater number of pounds per acre, (indeed almost double,) than I have ever seen recorded, is in its natural state, inferior to the average quality of cotton land, by at least one half. I might refer you, if necessary, to more than one hundred gentlemen, planters from Georgia and Alabama, who have examined my experiments carefully, and several of them at various stages of its growth, and with one general consent, pronounced it a fair test, and a great improvement. I have, from several stalks that grew on the three acres, in the proper places, taken 3½ to 4 lbs. of cotton, *carefully weighed*.—In the perfection of this improvement, yet in a state of great crudeness, when every stalk upon the acre (2940) *shall mature equally well*, what may I *reasonably* calculate to gather?

"——Nil desperandum,
Possunt quia, posse videntur."

N. B. Cloud, M. D.

Planters' Retreat, Ala., Dec. 26, 1842.

Infallible Cure for a Foundered Horse.—If your horse founders over night, in the morning take a pint of hog's lard, put it in a vessel and make it boiling hot, clean his hoofs well, set his foot in the lard. Heat it for each hoof boiling hot; take a spoon and put the fat over the hoof as near the hair as possible, and he will be fit for use in three hours if it is done early in the morning. It is better to remove the horse's shoe, but I have made several cures without. I have tried this on many horses during a period of fifteen years, and have never failed.

Lime for Fruit Trees.

The suggestions below as to the use of lime around fruit trees, are worthy of attention. In the autumn of 1841, we laid bare the roots of a number of unthrifty apple and peach trees, and left them exposed during the winter, returned the dirt in the spring, and applied to the roots of each tree about half a bushel of gas lime. Last year the trees seemed greatly improved, and the pears bore more than three times as much as they did the two previous years; the limbs had to be propped up, and the fruit seemed improved. We treated some old genuine trees in a similar manner, and the influence was obviously beneficial. Ashes are a good substitute for lime, and ordinary lime would probably do as well as the gas lime. Exposing the roots of trees occasionally during winter, it is well known, is very beneficial.—*D. Farmer.*

"The Peach Tree.—I have perfect faith in the beneficial use of calcareous substances applied to the roots of trees, sensible, as one of your correspondents has observed, that 'oxygen is the basis of acidity,' with which all putrid substances are charged: and it is with this view that Maj. Reybold, of Delaware, that first of cultivators of the peach, for he and his sons, and sons-in-law now number 78,000 peach trees planted in orchards, is at this time actively engaged in dressing his trees with shell-marl; by depositing a quantity at the root of every tree, to be pulverized by the frosts the ensuing winter. He also cultivates his orchards with the plough; turning a shallow furrow over the whole surface of the land, three times during the summer, a weighty affair, seeing that one of these orchards contains more than 100 acres; by these means he conceives that he renovates the land and benefits the health of the trees, which are indeed in full vigor, although many of them are very old, and the size of some apple trees of mature growth. I remember also that Mr. Dager, one of the proprietors of the lime quarry, mentioned at page 309 of the 4th vol. of the Cabinet, the lime from which was proved by analysis to yield 96.6 per cent of carbonate and not a trace of magnesia, increased the size of the fruit of an apricot tree three fold, by digging in around its roots a quantity of lime, adding also to its flavor in an equal degree. A. T. B.

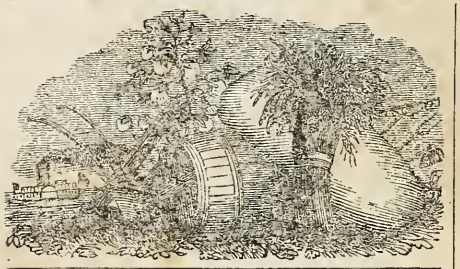
November 22, 1842.

Lime and Marsh Mud.—A gentleman distinguished for good and great qualities, tells us, that on a sandy soil, he has found lime a powerful fertilizer. A poor field put in corn—yield ten bushels—followed by oats--crop light--succeeded by wheat—yield not more than the seed—limed, and next crop gave 40 bushels to the acre. Experience has taught him the great value of *marsh mud*, especially when used in combination with a small quantity of lime. Keeps a small force especially assigned to the collection of marsh mud, weeds, leaves, mould from the woods, &c., and is amply compensated for it—cannot too highly recommend the use of marsh mud—has covered several acres with *brushwood*. The fertilizing effect very obvious, and thinks poor land may be reclaimed by a covering of brushwood, very speedily, and with great economy as to the labor and the results—is very careful to have all brush not large enough for fire wood, even the pruning of his orchards reserved to be spread upon the most exhausted portions of his land.

American Farmer.

Pruning.—Apple trees ought not to be pruned until the last of May or June; in the winter or until the last of May they ought not to be touched, and ought to be cut very close to the limb, the one cut from, or close to the body of the tree. The wound heals up immediately if cut off in May.—*Tennessee Agriculturist.*

Durable Rails.—Rails ought all to be split in April or May, when the bark will peel off the tree, and then the sap rails will last as long as the inside heart rails will. This is material to know.—*Tennessee Agriculturist.*



WEDNESDAY, MARCH 8, 1843.

TO SUBSCRIBERS.

We are frequently requested, by subscribers, to send them receipts for their subscription money. This is unnecessary, for we adhere strictly and rigidly to the CASH SYSTEM, and when the paper is sent it is conclusive evidence that it has been paid for.

☞ The delay occasioned in getting out our first number, has induced us to make an effort to issue the "Cultivator" weekly until we make up for the lost time, so as to make our volume end with the year, which is the most convenient season for subscribers to renew their subscriptions. When we have caught up, our issue will be regular every other Wednesday.

TO CORRESPONDENTS.

We must renew our entreaty to our friends to give us their views on all subjects pertaining to the business and system of agriculture. We are fully aware that many practical farmers, who are not in the habit of committing their views to writing, are in the possession of many valuable facts, the results of long experience, which if given to the public through the medium of the "Southern Cultivator," could not fail to be highly beneficial to the cause of agriculture, and we sincerely hope they will be prevailed on to furnish them for publication.

BOMMER'S PROCESS OF MAKING MANURE.

In obedience to the wish of an esteemed friend, we have transferred to our columns all the information we have been able to procure in reference to this important subject—which, we confess, is by no means satisfactory. This arises from the fact, that Mr. Bommer has obtained, from the government, a patent for his process, the secret of which is consequently with himself, and will be communicated alone to those who pay for the information. The favor with which it has been received by the committee, whose report will be found in this number, will certainly induce many planters to make the experiment, the result of which, when obtained, we shall take the earliest occasion to lay before our readers.

IRISH POTATOES.

The great value of this vegetable has induced us to present to the reader, in this number, the suggestions of several practical men upon the system of culture, as well as the best species of potatoe, which we commend to the consideration of all those who, like ourselves, feel that it is rather humiliating for us to import from the North and abroad such a large proportion of our consumption. The impression that the potatoe deteriorates in our climate after a few years, is, to a certain extent true; nevertheless our climate and soil are capable of producing a much better article than is generally found on our tables of home production, if the most approved system of culture be adopted.

COTTON CULTURE.

Cotton planters are referred to the extract of the letter of Dr. CLOUD, of Alabama, to the editor of the Albany Cultivator, on the subject of improving the culture of cotton. The writer assumes to speak from a practical experience of his system, and we hope that many of our cotton growers will test the experiment, to a greater or less extent, this season, as it is not yet too late. Many may cultivate one acre, and others can make a trial on a half or even a quarter of an acre of land, situate in a cotton field, which will satisfactorily test it as compared with the usual mode of culture. It is true the experiment of Dr. C. was made in a climate and soil, both better adapted to the culture of cotton than many portions of Georgia, yet if we can succeed in producing half the amount suggested by him, which to us seems rather extravagant, it will be a very important improvement, and worthy the consideration of every cotton planter, who by his present system of culture is impoverishing rather than improving his lands.

Messrs. EDITORS—We think it can be clearly shown, that labor can be more profitably employed, at present, in the improvement of the soil than in the cultivation of our great Southern staple. And by way of illustration, we will have to assume a basis, that four hundred pounds of cotton, or ten bushels of corn, is a fair average per acre for all the lands in middle Georgia; and the value of field labor is about fifteen cents a day, which is rather above the true value; and further, that land which will produce the amount above specified, is worth five dollars per acre.—Now we hold it true, that if an acre of land which produces, in the ordinary way of cultivation, five hundred pounds of cotton, or ten bushels of corn, is worth five dollars, an acre of land which will produce one thousand pounds of cotton, or thirty bushels of corn, would be worth fifteen dollars. We now propose to show, from the positions taken above, that by expending three dollars and ninety cents on an acre of common land worth five dollars, we have increased the value to fifteen dollars—thus realizing a clear profit, in the increased value of the land, of six dollars and ten cents, from a month's labor bestowed upon improvements, which is nearly one hundred per cent above the value of labor employed upon our farms in cotton culture. And that this will be the result, is clearly shown wherever the matter has been fairly tested.

But I think I have placed too low an estimate upon the production of an acre that has received a month's labor in improving; and in favorable years we should expect fifteen hundred pounds of cotton or forty bushels of corn. If these conclusions are correct, I think I have clearly demonstrated that labor employed in increasing the value of land, can be nearly doubly as profitably employed as in the growing of cotton. I know I have long established prejudices to combat, and plans that have grown old to contend with. Most of our planters say the thing is impossible; they have tried, and a complete failure has been the result. We think we know how the experiment has been made, and why there has been a failure: they have employed one hand and a team for six days in the three hundred and sixty-five in hauling manure, which, from exposure to the weather, had lost most of its valuable qualities; and this six days' labor was directed to a field of sixty acres. No wonder that what had been done would as well have been left undone. But this is not my plan. Bestow a month's labor on an acre in manuring, and if results even greater than those of my estimates are not realized, I shall in future cease to be a prophet.

In no instance where the experiment has been tried, has there yet been a failure; but results far above my estimates have been fully realized. We hear of more than five thousand pounds of cotton grown from an acre, and one hundred bushels of corn; and I have no doubt, if there was a premium offered for the greatest product per acre, either in cotton or corn, that many acres in Putnam county would grow over two thousand pounds of cotton, or fifty bushels of corn, where now not more than one-fourth is produced. But as no premiums are offered, I challenge any planter in Putnam county upon one acre of common upland to be grown in cotton the present year, to be submitted to the test of examination and admeasurement.

AGRICOLA.

Clopton's Mills, February 14, 1843.

Southern Recorder.

MORGANFIELD, UNION COUNTY, KY., January 9, 1843.

To the editor of the Louisville Journal:

GENTLEMEN:—Some time last winter, a number of farmers of this county, in the neighborhood of Mr. Milton Young, formed a society for the promotion of the farming interest, under the style of the "Union County Prize Association." One of the objects of this association was to test the fattening qualities of their hogs, and on the 19th of February, 1842, twelve of the members of the association met and agreed that each one of them should put up a pig, and the one who could make his pig gain the most flesh from that time until the 9th day of January, 1843, was to be entitled to the whole number put up. They accordingly went round to each of their respective houses on that day, weighed and put up their pigs.

Pursuant to the regulations of the association, the pigs (or as I may now term them, hogs,) were all slaughtered at 10 o'clock this morning and taken to Mr. Milton Young's, the place designated by rule of the association, and weighed at 12 o'clock by Mr. Aaron Waller, Leonard Clements and myself; and, by request of the association, I herewith transmit to you, for publication in your valuable paper, a statement showing the weight of each pig when put up, as well as the weight and ages of each when slaughtered.

Some of the members weighed their pigs for two or three months, at the end of each month, and it is to be regretted that this course had not been kept up throughout the time of feeding. I was informed that one of the pigs, during the time, gained in one month, when only about three months old, 98½ pounds.

Jonathan R. Hughes' and A. G. Ray's were by W. G. Hughes' Irish grazier and Berkshire boar, out of a sow of the common wood's stock. Milton Young's was by Grant Blackwell's Irish grazier and Berkshire boar, out of a sow of the common wood's stock; all the others were of the common wood's stock.

Thomas J. Robb's, (prize) weighed when put up, 19th February, 1842, 32 lbs.; weighed when slaughtered, 9th January, 1843, 499 lbs.; age when slaughtered, 1 year and 17 days; nett gain in 320 days, 467 lbs.

Jonathan R. Hughes' weighed when put up, 19th February, 1842, 19 lbs.; weighed when slaughtered, 9th January, 1843, 433½ lbs.; age when slaughtered, 1 year and 23 days; nett gain in 320 days, 414½ lbs.

Milton Young's weighed when put up, 19th February, 1842, 17 lbs.; weighed when slaughtered, 9th January, 1843, 432½ lbs.; age when slaughtered, 1 year and 1 day; nett gain in 320 days, 415½ lbs.

William McKinny's weighed when put up, 19th February, 1842, 24½ lbs.; weighed when slaughtered, 9th January, 1843, 423½ lbs.; age

when slaughtered, 1 year and 10 days; nett gain in 329 days, 400½ lbs.

Andrew W. Waller's weighed when put up, 19th February, 1842, 18 lbs.; weighed when slaughtered, 9th January, 1843, 423 lbs.; age when slaughtered, 1 year and 5 days; nett gain in 320 days, 405½ lbs.

A. G. Ray's, open sow, weighed when put up, 19th February, 1842, 23 lbs.; weighed when slaughtered, 9th January, 1843, 419 lbs.; age when slaughtered, 1 year and 23 days; nett gain in 320 days, 396 lbs.

Nathan H. Waller's weighed when put up, 19th February, 1842, 10 lbs.; weighed when slaughtered, 9th January, 1843, 367 lbs.; age when slaughtered, 11 months; nett gain in 320 days, 357½ lbs.

Yours, respectfully,

Willis G. Hughes.

P. S. The other five pigs put up died before the time of slaughtering.

THE PRODUCT OF CORN.

It must be evident to every intelligent corn grower, that the average product of corn is greatly below what it ought to be; and from the numerous large crops grown in various parts of our country, it must be equally so, and that nothing but proper manuring, preparation of the soil, and culture is wanting to bring about such an improvement as will give an average yield greatly above the present one. In several instances, nearly two hundred bushels have been grown on an acre, and in numerous others, largely above a hundred have been gathered from the same quantity of land, and these yields have been secured without any extraordinary expenditure of either manure or labor. The frequency of such results, should satisfy all reasonable minds that it is within the competency of good husbandmen to increase the present average product fully a hundred per cent. When we advance this opinion, we do it with a full knowledge and just conception of the responsibility we assume in so doing. We are aware that we may be thought as over sanguine by those who, from their boyhood up, have been in the habit of considering from four to six barrels to the acre as *good crops*, but in dispite of such conclusions, we here affirm it to be our fixed and deliberate opinion, that on good rich ground, well manured, deeply ploughed, thoroughly pulverized and judiciously worked, the crop of corn should yield from 80 to 100 bushels to the acre. Such ground, thus treated, would support a crop of corn four by two, two stalks in the hill; and such being the fact, we can see no just reason why every hill, planted in a prolific bearing corn, should not yield 1½ pint of corn: this would give 127 bushels. But suppose now, that each hill should give a pint, then the product would be 85 bushels. Such crops, some may say, are confined to small lots of a few acres in extent—not so; Mr. Earl Stimson has, for more than ten years in succession, averaged above a hundred bushels to the acre in crops of 5000 bushels. He to be sure plants closer than this, viz: 37 inches each way; but then his corn is of small variety, and will bear that distance in the climate of New York. If it be alleged, that corn planted four by two would subject the crop to firing, we reply, not without the culturist should commit the folly of cutting up the roots by deep ploughing, after the plants had attained sufficient size for the lateral roots to extend across the rows.—*American Farmer.*

CULTURE OF COTTON.

There are many around us who think the surface culture of cotton, or of crops, a new fangled notion, and scout at the idea. All encroachments on established usages and customs are received in this very way. There are others who think it has done and will do for the north, but will not in the south. I will state one circumstance, and close by citing one fact. In 1833, I think, I planted in the same field, about twenty acres of cotton, as usual barred off and scraped. The subsequent culture was entirely with the hoe and sweep, the latter merely shaved the surface, probably to the depth of one half to one inch; also three acres, and cultivated as was customary; plowing three times and hoeing.—There was but a path of eighteen to twenty-four inches dividing. Land as near similar as could be, only the first had been cleared five years, and the second piece only two years; therefore, the latter should have resisted the drought best. Mr. William Montgomery, my neighbor, a practical farmer of some thirty years' standing, ridiculed my notion, as I had been but recently from school. I took him into the field to look at it.—He admitted that the unplowed land was the best crop, and had sustained itself the best through the season, but could not account for it. Now every gardner knows the fact, that his garden returns him a greater income than any other spot he can cultivate. The plow never enters, nor is the earth disturbed two inches from March till July. He cultivates the surface entire, having previously spaded deep and manured well.—Then, if this be so in relation to raising vegetables of the tap root and horizontal root families in the garden, may it not be well to try it elsewhere, especially as more land can be cultivated and kept cleaner?—*Western Farmer.*

IRISH POTATOES.

Plant for late using the last of April, cover slightly and in a very deep furrow, about 18 inches apart, when just above ground cover them with the mould of one side the furrow, which will kill all grass and weeds, then when about 4 inches high, plough with a bull tongue plough four inches wide, twice in each furrow; plant from 12 to 16 inches in the drill; all that will be wanted afterwards, is to pull up any large weeds that grow in them, the shade of the stems and leaves will keep all grass under. To plant an acre in this manner, will take forty bushels of seed, and will produce from two to five hundred bushels to the acre on good land and well manured. The furrow when planted ought to be always the lowest, so the furrow may retain moisture.—*Tennessee Agriculturist.*

IRISH POTATOES.

This valuable vegetable, now much in use, is liable to deteriorate, as are many other productions of our soil. It is also capable of considerable improvement, in size and quality. The same seed, planted a few years in succession, will deteriorate. The signs of this deterioration are—1st. A quantity of blossoms appear on the stalks. 2d. The tuber is hard, watery and ill flavored. To remedy this, first let the cultivator gather the apples or pods from the top of the stalk—preserve the seed until the spring—plant or sow it in drills, in good or well manured ground—he will have potatoes of almost every hue, from the size of a pea to that of a partridge egg, the first year. These, if cultivated with care, will increase in size and be delightful in quality. I have tried the experiment.

I have tried another experiment, which is a shorter method, and perhaps equally efficacious. I took of that species called the "London Lady"—cut off what is called the seed end, threw that away, and planted the balance whole or cut in two—broke up my ground deep early in winter—opened furrows deep, 3 feet apart, dropped the potatoes from 9 to 12 inches apart—coevred first with manure, and threw up a ridge with a barshear plough. The culture was easy—to keep down grass or weeds was all that was necessary—and larger, more mealy, or better flavored potatoes were scarcely found in market than those I raised. The experiment is worth a trial.

I tried the Mashamock potatoe for two years—they disappointed my expectations. The second year they abounded in blooms, but the tubers were inferior. Among the "London Lady," whose seed ends I had cut off, scarcely a bloom appeared—they were fewer in quantity, but superior in size and quality.

I am decidedly opposed to "purchasing seed from the North"—1st. Because it is taking money out of our own country—and 2dly, Because seed from the North will deteriorate as soon as our own, and be no better. These conclusions are the result of actual experiment. And being now in a situation free from any interest in the culture of Irish Potatoes—only so far as eating is concerned—my testimony may be confided in.

L. Garrett.

Ib.

Potatoes.—M. Bellamy Aubert, of France, states, as the result of experiments continued during three seasons, that abundant crops of potatoes may be grown in poor claycy soils, by simply strewing the sets plentifully with rye-chaff previous to covering them with earth at planting.

Professor Voelker, of Erfwet, covers his potatoe sets with a layer of tanner's spent bark, two or three inches thick, before turning a furrow over them. He says he thus provides a loose spungy bed for the young tubers, prevents weeds from springing up and growing in immediate contact with the plants, and secures an abundant supply of moisture during the season, if but one soaking rain occur after planting—as the spent bark, covered by the surface soil, will retain water during the most protracted drought.

Mode of increasing the Growth of Potatoes.—The flowers being cut off as they appeared on the plants, the number of potatoes produced was much greater than where the blossoms had remained untouched. Early in October, the stems and leaves of the plant which had not bore flowers were strong and green; the others yellow and in a state of decay. The plants which had been stripped of flowers produced (on the same space of ground) about four times the weight of large potatoes, very few small ones being found. Those on which the flowers and fruit were left, produced but a small number of middle sized potatoes with a great number of little ones, from the size of a common filbert to that of a walnut.

SMUT IN WHEAT.

One word respecting smut in wheat. When I was first acquainted with this country, being a boy, the wheat raised here was all smutty, so much so that it required to be washed before it was fit to use. The first year we sowed the wheat procured in the neighborhood, which was smutty. The next season some for seed was procured from a distance, clean of smut; this wheat was washed clean, and while wet, as much good ashes was mixed with it as would stick to the wheat, and sown immediately. The crop was clean of smut, and for more than twelve years in succession we practised the same way on the farm. We procured wheat clean of smut, washed and ashed the seed, and during the whole time never raised a crop of smutty wheat. I have more than once sown beside my neighbor's lot, nothing but a fence dividing us—he sowed his wheat dry and I as I have stated—his was very smutty, mine quite clean. All this time winter wheat was sown and occasionally spring wheat; and to this time, which is more than sixty years, I never have raised a crop of smutty wheat, when I observed the above rule; or procured wheat clean of smut, ashed, &c.—Once I had some spring wheat somewhat smutty; and it was from smutty seed. For a number of years of the time I speak of, there was no lime in the country, otherwise lime would have been used instead of ashes, as we have done since lime has become plenty.

A Claremont Farmer.

American Farmer.

Cholic in Horses.—I was told lately by a gentleman of Prince George county, that a tea-cup full of spirits of turpentine would give instant relief to horses laboring under this disorder. He added, that on one occasion, all the *oxen* of two of his carts were *hoven*—that is, as you know, suddenly swollen by the generation of gas in the stomach, from eating green food. The overseer expected all would die, when our informant ordered a tea-cup full of spirits of turpentine, diffused in oil, to be given to each. The relief was in every case *instantaneous* and effec-

tual, almost before he could have thought there was time to swallow. Such facts should always be communicated for wide diffusion and preservation, in agricultural journals.—*Am. Farmer.*

HINTS TO FARMERS.

A farmer should never undertake to cultivate more land than he can do thoroughly; half tilled land is growing poorer; well tilled land is constantly improving.

A farmer should never keep more cattle, horses, sheep or hogs, than he can keep in good order; an animal in high order the first of December, is already half wintered.

A farmer should never depend on his neighbor for what he can, by care and good management, produce on his own farm; he should never beg fruit while he can plant trees, or borrow tools when he can make or buy them—a high authority has said the borrower is servant to the lender.

A farmer should never be so immersed in political matters as to forget to sow his wheat, dig his potatoes and bank them up in his cellar, nor should he be so inattentive to them as to be ignorant of those great questions of national and State policy which will always agitate, more or less, a free people.

No farmer should allow the reproach of neglected education to lie against himself or family; if "knowledge is power," the commencement should be early and deeply laid in the minds of his children.

A farmer should never use intoxicating liquors as a drink; if, while undergoing severe fatigue and the hard labor of the summer, he would enjoy robust health, let him be temperate in all things.

A farmer should never refuse a fair price for anything he wants to sell; we have known a man who had several hundred bushels of wheat to dispose of, refuse eight shillings and six pence, and after keeping his wheat six months, was glad to get six shillings for it.—*Far. Cabinet.*

TRANSLATIONS FROM THE GERMAN.

Grape Vine Cuttings.—The superintendent of the gardens of the Duke of Weimar, employs with success, the following method of propagating the more choice varieties of wine and table grapes, by means of cuttings. He selects from among the stalks and branches cut away in fall and spring, such as are of suitable diameter—say from ⅜ to ½ inch—and have well ripened wood. These he cuts in pieces in midway between the buds, and splits each piece lengthwise, preserving the bud uninjured. The halves containing the buds are then placed with the flat side on a bed of well prepared garden mould, gently pressed down level with the surface, and covered with moss, or a layer of fine leaf mould. Thus planted, the cuttings speedily strike root, if the bed be kept moist by occasional waterings, and properly shaded, without obstructing the circulation of the air.

Cuttings similarly prepared, though not split, readily strike root and produce vigorous plants, if their ends be dipped in melted sealing-wax, and they be planted in good garden soil, covering them in to the depth of half an inch. The ground must be kept moist, and free from weeds.

Grafting.—M. Schroer recommends using a branch of common willow, an inch or two in diameter, in the following manner, as a matrix for receiving the grafts of such variety if apple, pear or quince trees, as it is desirable to multiply. Make longitudinal cuts or slits *through* the branch, at equal distances of 15 or 18 inches.—Take grafts having two perfect buds, give the lower end the usual wedge shape, using a keen knife, and insert them in the slits of the willow, making the lower bud sit close to the slit. Then bury the branch in a trench formed in good garden soil of such depth as will permit the upper buds to protrude just above the surface of the ground, when the trench is again filled. The ground must be watered occasionally if the season be dry, and weeds must be carefully extirpated whenever they appear. In the spring of the following year, the branch may be taken up and cut in pieces, leaving a small portion to each of the growing grafts—which are to be replanted in a nursery. The willow does not form a permanent union with the grafts, but merely supplies nutriment till the proper fibrous roots are produced from the lower bud.

Horse Shoes.—Many of the readers of the Cultivator are aware that some two or three years since, a patent was taken out by Mr. Burden, of Troy, for machinery intended to manufacture horse shoes. Circumstances prevented Mr. Burden from perfecting his plans at the time, and it has not been until lately, that he has found leisure to return to the subject. He has done it, however, and the result is that with his machinery he is able to produce a more perfect shoe than can be made in any other way, with a rapidity which may well astonish those accustomed only to the former slow and laborious methods. The regulating the size of the shoe, punching the nail holes, turning the heel corks, forming and welding on the steel toe corks, are all performed by machinery, and with a perfection and accuracy the eye and hand are unable to attain. Five different sized shoes are turned out by machinery, thus securing a proper fit to feet of different sized horses, without heating or other trouble. Mr. Burden uses none but the very best Swedes iron, of consequence the quality of his shoes will be first rate.

There are probably very few who have properly considered the importance of the horse shoe manufacture to the country, or the quantity of iron consumed in that product. The census gave the number of horses at about four millions three hundred thousand. For the whole, it will not be too much to allow two sets of shoes annually, which at the ordinary weight of horse shoes, would use at least twenty-five thousand tons of iron and steel. It is very probable the shoes of Mr. Burden will soon be found occupying the market extensively, if not exclusively, and the estimate has been made that by their adoption, the cost of shoeing horses can be reduced one half. Any saving of this kind will be extensively and beneficially felt, and by none more so than by the farmer.—*Cultivator.*

Press for Working over Butter.—Smooth as perfectly as possible a piece of hard wood plank, 18 inches wide and 24 long. On both sides and end, nail pieces of board, rising one inch above the surface. Near the open end screw in a small ring-bolt, or what is better, three; one at each corner and one in the centre. Let the ring on the bolt be one inch in diameter. Make a brake 35 inches long, 9 inches of which is for the handle. Let it be 3½ inches wide, 1½ thick; one edge made sharp, and the other rounded. On the end to go next the eye-bolts put a ring, and in the centre screw a bolt with a head, which will just slip through the eye of either of the ring-bolts. The bolts should be screwed into the plank, so that when the brake is attached, its edges will exactly fit to the surface the whole length.

Need I say more? The rest is plain. Give the end next you a slight elevation; and by using the brake as a braker does his, and by changing as occasion requires, all the milk may be worked from butter with a trifling labor.

A marble slab would be preferable, as the butter would stick less to the surface. A small wooden shovel three inches square, with the edges perfectly straight, should be at hand to keep all in place. James Bates.

[*Cultivator.*

Destruction of Moles.—The following recipes for destroying moles, we extract from an English work by Charles Fothergill, of Salisbury, England.

1. Make a paste with powdered hellebore roots, wheat flour, and ground glass; place it near their holes to eat, and you will soon destroy them.

2. Make a mixture of brimstone, rosin and turpentine, put them into a horn with a narrow neck, first enveloping the same in tar; set fire to the tow thus prepared; then insert the mouth of the horn into the burrow of the mole, and he will soon be suffocated to death.

AUGUSTA MARKET.

[Reports of our Market.—In commencing this department of the "Cultivator," we deem it proper to remark, that in order to render it most valuable to the readers, our information will be always obtained from the most authentic sources, and as we are not interested in any department of trade, or in any bank, our reports of the market and the value of money may be relied on implicitly.]

Wednesday A. M., March 15.

Cotton—The market for the last week has been remarkably quiet, and both holders and dealers seem disposed to await the arrival of later accounts from Europe, which have been daily expected for the last week, before they operate to any considerable extent. The prices, which are almost nominal, range from 5¾ to 6¼ cents as extremes of the market—principal sales 4½ to 5¾ cents.

Trade, &c.—The inactivity in the cotton market has materially influenced the operations in trade in every other department. The stocks of our merchants are, however, very good, and what with the additions now daily making, will soon be very complete, at prices unprecedentedly low.

Exchange and Money—Exchange is at par on all points North and East of us. Central money ranges at 25 to 30 per cent discount. Exchange Bank of Brunswick, the Phœnix and Commercial Banks of Columbus, and the Hawkinsville Bank, are in very bad odor, and generally regarded by our most astute business men as unworthy of credit.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, invariably in advance. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

Advertisements pertaining to agriculture will be inserted for one dollar for every square of twelve lines, or less, for the first insertion, and seventy-five cents per square for each continuance.

☞Post Masters are authorized to receive and forward money free of postage.

☞All communications must be post paid.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., MARCH 22, 1843. No. 3.

REMARKS ON THE MANUFACTURE OF CORN-STALK SUGAR.

BY WILLIAM WEBB, OF WILMINGTON, DELAWARE.

The most profitable application of labor is a desideratum too frequently overlooked or disregarded by those who attempt the introduction of new manufactures into a country. All calculations of advantage which is to result from the production of any article must be made with due regard to this point, or practice will prove them to be erroneous.

Fully impressed with this truth, the most rigid examination is invited into every thing now offered; so that, as far as possible, we may arrive at a correct decision respecting the real value of the proposed manufacture. In common with many others, I have felt considerable interest in the plan for extending the cultivation of sugar in temperate climates, and have made many experiments, first upon the beet, and recently upon maize or Indian corn, in the hope of discovering some mode by which the desired end might be attained.

The results from the latter plant have been extremely encouraging. The manufacture of sugar from it, compared with that from beet, offers many advantages. It is more simple, and less liable to failure. The machinery is less expensive, and the amount of fuel required is less by one-half. The quantity of sugar produced on a given space of ground is greater, besides being of better quality. An examination into the nature and productive powers of these two plants will show that no other results could have been reasonably expected. It is a well-established fact, that every variety of production found in plants is derived from the sap. It is also ascertained that the principal substance found in the sap or juice of many vegetables is sugar. Therefore, the amount of saccharine matter produced by any plant of this description may be estimated from an analysis of the fruit, seed, &c., of such plant when ripe. The grain yielded by corn, and the seed from beet, in the second summer of its growth, are nothing more than this sap or juice elaborated by the process of vegetation, and presented to our view in another form.

Now, as it is contrary to the economy of nature to suppose that there should be any loss of nutritive matter in this change of sap into seed or grain, does it not follow that there must be the same difference in the quantity of sugar produced by the two plants as there is between the nutritive properties of beet seed and corn?

The juice of maize contains sugar, acid and a gummy mucilaginous matter, which forms the scum. From the experiments of Gay Lussac, Thenard, Kirchoff and others, [it is proved,] that starch, sugar and gum, are extremely similar in composition, and may be as readily converted into each other, by chemical process, as they are by the operation of nature. For example: starch boiled in diluted sulphuric acid, for thirty-six hours, is converted into sugar of greater weight than the starch made use of.

This result goes to show that every pound of starch found in the seed of a plant has required for its production at least one pound of sugar, in the form of sap. If it be objected that this deduction is too theoretical to be admitted, it may be answered that experiment, so far as it has gone, has fully attested its correctness.

The raw juice of maize, when cultivated for sugar, marks 10° on the saccharometer; while the average of cane juice (as I am informed) is not higher than 8°, and beet juice not over 3°.

From 9¾ quarts (dry measure) of the former. I have obtained 4 pounds 6 ounces of syrup, concentrated to the point suitable for crystallization. The proportion of crystallizable sugar appears to be larger than is obtained from cane juice in Louisiana. This is accounted for by the fact, that our climate ripens corn perfectly, while it but rarely if ever happens that cane is fully matured. In some cases the syrup has crystalized so completely, that less than one-sixth part of molasses remained. This, however, only happened after it had stood from one to two months. There is reason to believe, that if the plant were fully ripe, and the process of manufacture perfectly performed, the syrup might be entirely crystalized without forming any molasses.

This perfection in the manufacture cannot, however, be attained with the ordinary apparatus. Without any other means for pressing out the juice than a small hand-mill, it is impossible to say how great a quantity of sugar may be produced on an acre.

The experiments have been directed more to ascertain the saccharine quality of corn-stalk than the amount a given quantity of ground will produce; but the calculations made from trials on a small scale leave no room to doubt that the quantity of sugar will be from 800 to 1600 lbs. This amount will not appear unreasonable, when it is considered that the juice of corn is as rich as that of cane, and the weight of green produce at least equal.

Mr. Ellsworth, in one of his publications, states, as the result of actual weighing and measuring, that corn, sown broadcast, yielded five pounds of green stalks per square foot; this is at the rate of 108½ tons to the acre.

My attention was first directed to maize as a material for sugar, by observing that, in some stalks, the juice was extremely sweet, while in others it was weak and watery. On examination, it appeared that the latter had borne large and perfect ears and grain, while, on the former, these were either small in size or entirely wanting. The natural conclusion from this observation was, that if the ears were taken off in their embryo state, the whole quantity of saccharine matter produced by the process of vegetation would be preserved in the stalk, from which it might be extracted when the plant was matured. But the idea occurred too late in the season to test it by experiment. A few stalks, however, were found, which, from some cause, had borne no grain; these were bruised with a mallet, and the juice extracted by a lever press. Some lime was then added, and the desiccation, evaporation, &c., began and finished in a single vessel. By these simple means, sugar of a fair quality was produced, which was sent to the horticultural exhibition of our society in 1840.

I have since been informed, through Mr. Ellsworth, that Mr. Hallas, of France, had discovered, in 1839, that the saccharine properties of maize were increased by merely taking off the ear in its embryo state. An experiment, however, which I instituted, to determine the value of this plan, resulted in disappointment; the quantity of sugar produced was not large enough to render it an object. The reasons of this failure will be sufficiently obvious on stating the circumstances. It was found that taking the ear off a large stalk, such as is produced by the common mode of cultivation, inflicted a considerable wound upon the plant, which injured its health, and of course lessened its productive power. It was also found that the natural disposition to form grain was so strong, that several successive ears were thrown out, by which labor was increased, and the injuries of the plant multiplied. Lastly, it appeared that the juice yielded from those plants contained a considerable portion of foreign substance, not favorable to the object in view. Yet, under all these disadvantages, from one hundred to two hundred pounds of sugar per acre may be obtained.

The manifest objections detailed above suggested another mode of cultivation, to be employed in combination with the one first proposed; it consists simply in raising a greater number of plants on the same space of ground. By this plan, all the unfavorable results above mentioned were obviated, a much larger quantity of sugar was produced, and of better quality. The juice produced by this mode of cultivation is remarkably pure and agreeable to the taste.—Samples of the sugar yielded by it are now in the Patent Office, with a small hand-mill by which the stalks were crushed. Some of the same kind was exhibited to our agricultural society in October, 1841, accompanied by an answer to an invitation from its president, Dr. J. W. Thompson, to explain the mode of culture and process of manufacturing the sugar. The molasses, after standing as before mentioned, from one to two months, became filled with small crystals, which, on being drained, exhibited a peculiar kind of sugar; the grain is small, and somewhat inferior in appearance, but still is as sweet and agreeable to the taste as can be desired. A small sample of this sugar I have brought for your inspection. This product, from what was thought to be molasses, is a new and unexpected discovery, and discloses an important fact in the investigation of this subject. It shows the superior degree of perfection attained by the corn plant, compared with the cane, in any part of the Union. It is generally understood that the latter cannot be fully matured in any except a tropical climate, and the proportion of molasses obtained from any plant is greater or less according to the immaturity or perfection of its growth. The sweetness of the corn-stalk is a matter of universal observation. Our forefathers, in the revolutionary struggle, resorted to it as a means to furnish a substitute for West India sugar. They expressed the juice, and exerted their ingenuity in efforts to bring it to a crystalized state, but we have no account of any successful operation of the kind. In fact, the bitter and nauseous properties contained in the joints of large stalks render the whole amount of juice from them fit only to produce an inferior kind of molasses. I found, on experiment, that by cutting out the joints, and crushing the remaining part of the stalk, sugar might be made, but still of an inferior quality. The molasses, of which there was a large proportion, was bitter and disagreeable.

From one to two feet of the lower part of these stalks was full of juice, but the balance, as it approached the top, became dryer, and afforded but little. From the foregoing experiments we see that, in order to obtain the purest juice, and in the greatest quantity, we must adopt a mode of cultivation which will prevent

the large and luxuriant growth of the stalk.—As we are upon the threshold of this inquiry, many other improvements may be expected in the mode of operation; for example, it may be that cutting off the tassel as soon as it appears on the plant will prevent the formation of grain, and prove a preferable means for effecting that object.

On the whole, there appears ample encouragement for perseverance. Every step in the investigation has increased the probabilities of success; no evidence having been discovered why it should not succeed as well, if not better, on a large scale, than it has done on a small one.

1. In the first place, it has been satisfactorily proved, that sugar of an excellent quality, suitable for common use without refining, may be made from the stalks of maize.

2. That the juice of this plant, when cultivated in a certain manner, contains saccharine matter remarkably free from foreign substances.

3. The quantity of this juice (even supposing we had no other evidence about it) is sufficiently demonstrated by the great amount of nutritive grain which it produces in the natural course of vegetation. It is needless to expatiate on the vast advantages which would result from the introduction of this manufacture into our country.

Grain is produced in the west in such overflowing abundance that the markets become glutted, and inducements are offered to employ the surplus produce in distillation. This business is now becoming disreputable. The happy conviction is spreading rapidly, that the use of alcohol as a beverage, instead of conducing to health and strength, is the surest means of destroying both. Some other production, therefore, will be required, in which the powers of our soil may be profitably employed. This, it is hoped, will be found in the business now proposed. Instead of distilleries, converting food into poison, we may have sugar-houses, manufacturing at our doors an article in universal demand, not merely useful, but necessary, furnishing as it does one of the most simple, natural and nutritious varieties of human sustenance found in the whole range of vegetable production.

It is said that the general use of sugar in Europe has had the effect to extinguish the scurvy and many other diseases formerly epidemical. It may be doubted whether a tropical country can ever furnish a great amount of exports, except through the means of compulsory labor.—It appears, then, highly probable, that if the inhabitants of temperate countries wish to continue the use of sugar, they must find some means to produce it themselves. The beet appears to succeed well in Europe, and the manufacture from it is extending rapidly; but there is no hazard in making the assertion that Indian corn is far better adapted to our purpose. The following mode of cultivating the plant, and making the sugar, is the best that can now be offered. The kind of soil best adapted to corn is so well understood, that no directions on this point are necessary, except that it should be rich—the richer the better; if not naturally fertile, manure must be applied, either ploughed in or spread upon the surface, or used both ways, according to the ability of the owner. Nothing can form a better preparation for the crop than a clover sod well turned under and harrowed fine immediately before planting.

Select for seed the largest and best ears of any variety of corn not disposed to throw up suckers or spread out in branches; that kind most productive in the neighborhood will be generally the one best adapted to the purpose. The planting should be done with a drilling machine. One man, with a pair of horses and an instrument of this kind, will plant and cover, in the most perfect manner, from ten to twelve acres in a day. The rows (if practicable, let them run north and south) two and a half feet apart, and the seed dropped sufficient thick in the row to ensure a plant every two or three inches. A large harrow, made with teeth arranged so as not to injure the corn, may be used to advantage soon after it is up. The after culture is performed with a cultivator, and here will be perceived one of the great advantages of drilling: the plants all growing in lines, perfectly regular and straight with each other, the horse-hoe stirs the earth and cuts up the weeds close by every one, so that no hand-hoeing will be required in any part of the cultivation. "It is part of the system of cane planting in Louisiana, to raise as full a stand of cane upon the ground as possible, experience having proved that the most sugar is obtained from the land in this way." As far as my experience has gone, the same thing is true of corn. This point must therefore be attended to, and the deficiencies, if any occur, made up by timely replanting.

The next operation is taking off the ears.—Many stalks will not produce any; but whenever they appear, they must be removed. It is not best to undertake this work too early, as when the ears first appear, they are tender, and cannot be taken off without breaking, which increases the trouble. Any time before the formation of grain upon them will be soon enough.

Nothing further is necessary to be done until the crop is ready to cut for grinding. In our latitude, the cutting may commence with the earlier varieties about the middle of August. The later kinds will be ripe in September, and continue in season until cut off by frost. The stalks should be topped and bladed while standing in the field. They are then cut, tied in bundles and taken to the mill. The top and blades, when properly cured, make an excellent fodder, rather better, it is believed, than any hitherto used; and the residuum, after passing the rollers, may easily be dried and used in the same way—another advantage over the cane, which, after the juice is expressed, is usually burned

The mills should be made on the same general principle employed in constructing those intended for grinding cane. An important difference, however, will be found both in the original cost and in the expense of working them. Judging from the comparative hardness of the cane and corn-stalk, it is believed that one-fourth part of the strength necessary in the construction of a cane mill will be amply sufficient for corn, and less than one-fourth part of the power will move it with the same velocity. It may be made with three upright wooden rollers, from twenty to forty inches in length, turned so as to run true, and fitted into a strong framework, consisting of two horizontal pieces, sustained by uprights. These pieces are mortised, to admit wedges on each side the pivots of the two outside rollers, by which their distance from the middle one may be regulated. The power is applied to the middle roller, and the others are moved from it by means of cogs. In grinding, the stalks pass through on the right side of the middle cylinder, and come in contact with a piece of frame work called the dumb returner, which directs them backwards, so that they pass through the rollers again, on the opposite side of the middle one. The modern improved machine is made entirely of iron, three horizontal rollers, arranged in a triangular form, one above and two below; the cane or stalk passes directly through, receiving two pressures before it escapes. The lower cylinders are contained in a small cistern which receives the juice. The latter machine is the most complete; the former the least expensive. These mills may be moved by cattle; but, for large operations, steam or water power is preferable. When the vertical cylinders are turned by cattle, the axis of the middle one has long levers fixed across it, extending from ten to fifteen feet from the centre. To render the arms firm, the axis of this roller is carried up to a considerable height; and oblique braces of wood, by which the oxen or horses draw, are extended from the top of the vertical axis to the extremities of each of the arms. When horizontal cylinders are propelled by animal power, the upper roller is turned by the cogs at one end, which are caught by cogs on a vertical shaft. It is said that, in the West Indies, the purest cane juice will ferment in twenty minutes after it enters the receiver. Corn juice has been kept for one hour before boiling, without any apparent injury resulting; but so much delay is not desirable, as it may be attended with bad effects.

The process which has been employed in the manufacture of maize sugar is as follows: The juice, after coming from the mill, stood for a short time, to deposite some of its coarser impurities. It was then poured off and passed thro' a flannel strainer, in order to get rid of such matters as could be separated in this way. Lime water, called milk of lime, was then added, in the proportion of one or two table spoons full to the gallon. It is said by sugar manufacturers, that knowledge on this point can only be acquired by experience; but I have never failed in making sugar from employing too much or too little of the lime. A certain portion of this substance, however, is undoubtedly necessary, and more or less than this will be injurious; but no precise directions can be given about it. The juice was then placed over the fire, and brought nearly to the boiling point, when it was carefully skimmed—taking care to complete this operation before ebullition commenced. It was then boiled down rapidly, removing the scum as it rose. The juice was examined, from time to time, and if there was any appearance of feculent particles, which would not rise to the surface, it was again passed through a flannel strainer. In judging when the syrup is sufficiently boiled, a portion was taken between the thumb and finger; and if, when moderately cool, a thread half an inch long could be drawn, it was considered to be done, and poured into broad shallow vessels to crystalize. In some cases crystalization commenced in twelve hours; in others, not till after several days; and in no case was this process so far completed as to allow the sugar to be drained in less than three weeks from the time of boiling. The reason why so great a length of time was required I have not yet been able to discover.—There is no doubt but that an improved process of manufacture will cause it to granulate as quickly as any other.

Enough has been said to enable any one so disposed to manufacture sugar from maize.

As to the profits of the business, I shall make no positive assertions; experience on the subject is yet too limited to warrant them; and as all the facts in relation to it are now before the public, every one interested can draw his own conclusions. It is said, by those acquainted with the cultivation of the cane, that that business cannot be carried on profitably on less than one hundred acres in crop; and that attempts on a small scale will be certain to fail, with a great loss of time and labor. How far this may be applicable to corn remains to be seen.

Some comparison between the cultivation of cane and that of corn may perhaps be interesting.

The cane lands in Louisiana are redeemed to agriculture by strong embankments along the river, and by numerous ditches, which extend back into the swamp to a considerable distance beyond the line of cultivation. The ground is still further divided, by smaller ditches, into lots of from one to two acres in extent. It is extremely rich and productive, but the expense of draining and keeping up the embankments must be considerable; this forms the first difference to be noted in the culture of the two plants under consideration.

The best season for planting cane in Louisiana is in the fall, which is also the time of harvest, when labor is the most valuable, and the greatest exertions are required to secure the crop before it is destroyed by frost.

But the most striking difference will be found in the cost of seed, and in the labor of planting. The cane is propagated by layers; these are partly furnished from the tops of the plants, when cut for grinding, but are principally ratoons. Of the latter it requires the produce of one acre to plant three. The grain from one acre of corn

will be sufficient for planting forty acres; therefore the difference in the expense for seed will be as one to thirteen

In planting cane, furrows are made with the plough from two and a half to three feet apart; in these the layers are placed, in a double row, and the earth drawn over them, with hoes, to the depth of three or four inches.

In the spring, before the plants are up, this covering is partly scraped off, so as to leave them buried from one to two inches. From this account it is evident that no more manual labor will be required to drill fifty acres in corn, than to plant one acre in cane. The labor of cultivating the latter plant during its growth is also greater, but this may be balanced by the extra work required to take off the embryo ears from the corn. When cultivated in the mode recommended, the stalk of corn is soft, remarkably heavy, and full of juice from bottom to top.—The amount of power required for grinding them must be much less than is necessary for cane, or, what is the same thing, an equal power will do it with greater rapidity. The average yield of cane, in Louisiana, is one thousand pounds of sugar and forty-five gallons of molasses per acre. From the above comparative statement, it would appear that one-half this amount of crop from corn would be equally if not more profitable.

I will only add, in conclusion, that whether or not the sugar from the corn-stalk may soon become an article of profitable export, its manufacture in the simplest form will enable every family to supply themselves with this article for common use, now become so much a necessary of life, and thus save a considerable bill of expense yearly paid for foreign sugars.

—

*Extract from Annales de la Societe Polytechnique, Practique No. 22, for October, 1839.**

Sugar or Corn.—There is no plant of greater interest or utility than Indian corn. It can serve, under a great variety of different forms, for the nourishment of man and the domestic animals, and above all, the application of industrious science.

In reference to its saccharine qualities, maize has not been sufficiently appreciated. Travellers report that under the tropics the stalk of this plant is so very saccharine that the Indians suck it as in other places they do the sugar cane. M. Pallas, who has made a great many researches on this application of maize, has arrived at a remarkable result; he has found by many experiments, both in France and more recently in Africa, that this vegetable, by a simple modification applied to its culture, is able to furnish a much more considerable quantity of sugar than by the ordinary method. This method consists in detaching from the plant, immediately after the fecundation of the ovaries, (after the plant has tasselled,) the young ear, and to leave it to develop itself, thus deprived of its fruit. Arrived at maturity, the stalk of Indian corn contains crystalizable sugar in quantity very often double that obtained when the plant is left to mature with the grain. In fact, by the ordinary mode of culture, the grain is nourished at the expense of the sugar in the stalk, as it absorbs a great quantity of this immediate principle, which, by the process of nutrition, is converted into starch. On the other hand, if the young ears are immediately destroyed, the sugar intended to nourish them remains in them, where it accumulates, and the maize plant is thus converted into a true sugar cane, while the fibrous part can be manufactured into paper.

The quantity of sugar is so very great in the stalk of the maize, deprived of the ear, that the pith of this vegetable retains a sensible flavor of sugar, even after it has been dried, as is easily proved by examining the specimens deposited by M. Pallas in the bureau of the Academy of Sciences. These results are so important as to merit experiments on a grander scale, which may obtain thus for France a source of new industry in the manufacture of sugar.

H. L. Ellsworth.

*Translated at the Patent Office, and highly conformatory of Mr. Webb's essay.

—

No. 4.

Dear Sir:—Your favor is duly received. You request to know the best method of crystalizing corn syrup, and I know of no more ready method to afford the information required, than to detail the entire mode which should be pursued for its manufacture:

1st. To cut the cane as ripe as possible, but before any acetic acid is formed: litmus paper, touched to the fresh cut cane, will turn red if acid.

2d. Express the juice without loss of time, as every moment after cutting will deteriorate its quality.

3d. A small quantity of clear lime water (say one quart to a hundred gallons of juice) should be added the moment it is expressed, unless the juice shows acidity with litmus paper; in that case, too, lime should be used, but a solution of sal soda or soda ash, should be added, until it is precisely neutral.

4th. When the juice is neutral (free from excess of acid or alkali) it should be evaporated in such an aparatus as would finish its change in thirty minutes, if the boiling power is too small good crystalization cannot possibly be obtained.

The whole time occupied from the cutting of the cane to finishing its boiling should not exceed one hour.

5th. *To know when the boiling is finished*, place a thermometer in the kettle, and continue to evaporate until it stands at 239° Farenheit.—If, when placed to run off after cooling, it should be found too freely boiled, the next time boil to 240°, or, if too light to run off, to 238°, and so on.

6th. The kettle or boiler should be so arranged that the moment it is done its charge should be thrown into a cooler, capable of holding a number of charges. The first charge should be left in the cooler, without stirring, until the second charge is thrown in; then with an oar scrape the crystals found on the side and bottom of the cooler loose, and gently stir the whole mass together, (the less stirred the better,) so continue, at the letting in of each charge, to stir gently; and when all is in the cooler, let the whole stand until it cools down to 175°; then fill out into sugar moulds of a capacity not less than 14 gallons. When cooled in the mould sufficient, (say fourteen hours,) pull the plug out of the bottom of the mould, and insert a sharp point, nearly as large as the hole, some six inches; withdraw the point, and stand the mould on a pot to drip.

7th. If the sugar is intended to be brown, leaving it standing on the pot for a sufficient length of time, in a temperature of 80°, will run off its molasses, and leave it in a merchantable shape; it will probably require twenty days. It can then be thrown out of the moulds, and will be fit for use. When moulds cannot be obtained, conical vessels of wood or metal with a hole at the apex, will answer equally as well.

The above description will be sufficient for any operator, if strictly followed; but should any of your friends wish to make the experiment on a large scale, or to produce white instead of brown sugar at a single operation, they had better see me personally before commencing, as the kind of kettle, and many other minor particulars, will be important. The above description, however, is fully sufficient for the use of the farmer. If the juice of the cornstalks be manufactured with the rapidity named in the former part of this letter, no clarification will be necessary, and scum which may rise during the boiling can be taken off with a skimmer; but in the *large way*, both clarification and filtration would be requisite, as in large operations every part of the kettle cannot be got at to skim. Since I last saw you, I have made some experiments on the cornstalk; and if your statements are correct as to the quantity of juice which can be obtained from the acre, then there can be no doubt of its entire superiority over the sugar cane. I fear, however, that the enthusiasm of those who made the experiments you spoke of has led them into error. It is true that the juice of the cornstalk, grown with a view to sugar making, will yield a juice at 10° Baume. I have made arrangements to try the experiments fully in the coming summer, and when done will communicate the results. I remain, sir, yours respectfully,

J. J. Mapes.

Hon. H. L. Ellsworth.

—

REMEDY FOR COLIC IN HORSES.

Take two quarts of cold water in a hand basin, add with your fire-shovel say a pint of hot wood ashes or embers, and stir. Cut off an inch and a half from a common hand of tobacco, and shred in the mixture—stir all up, and let it stand fifteen minutes and settle. Pour off a common black bottle full of the fluid and drench your horse—in half an hour he will be well.

Rationale.—The gas which bloats the horse is probably carbonic acid gas and light-carburetted hydrogen, the product of the vegetable decomposition which is going on in the intestines—at any rate it is a gas which is immediately absorbed by its combination with an alkali.—The tobacco is a powerful anti-spasmodic and cathartic—it, therefore, prostrates the nervous sensibility, checks the inflammation and increases the action of the lower intestines. In a critical or extreme case, it will be well to give an enema of a strong decoction of tobacco with a common syringe. Out of more than one hundred instances, in which I have seen this remedy used, I have yet to witness the first failure. It also has an advantage over very many remedies, viz: it cannot injure a horse in perfect health. Feed light for a day or two.

Causes of Colic.—The main cause consists in the presence of a greater amount of food than the intestines can elaborate into nutriment, or of a kind of food difficult of digestion, producing spasm, obstruction, vegetable decomposition and consequent inflammation. *Hard driving on a full stomach* will produce colic, because the effort weakens the tone of the digestive powers, and they cannot elaborate the food—which then produces irritation and inflammation. *Cold water when the horse is heated*, because it is a powerful stimulus, and will produce spasm or obstruction, or by the re-action produces weakness of the digestive organs. It also gives too much fluidity to the food—fluids are more difficult of digestion than solids. It also increases the fermentation. *Hearty feeding after hard driving*, because the stomach and intestines sympathize with the general fatigue of the system, and are easily overloaded, and the appetite will induce the horse to eat more than he can digest.

Colic is first flatulent, then inflammatory. In the flatulent stage, or in what is called belly-ache, aromatic remedies or half a gill of spirits of turpentine, or a pint of whiskey and black pepper may be given; all these stimulate the system, and may assist it in overcoming the difficulty. But in the latter and inflammatory stage, which rapidly succeeds the former, these same remedies would produce speedy death by increasing the inflammation. In nine cases out of ten, this disease is not observed by the ordinary driver until it has assumed the inflammatory form—in which stage the remedy at the head of this article should be given with as little delay as possible; although it should not be omitted even if the horse be supposed to be in the article of death itself—for I have seen them recover when every by-stander had dismissed all hope. Yours truly, T. N. Welles.

French Creek, Peoria Co., Nov. 25, 1842.

P. S.—*Change of feed* will sometimes produce colic, for the reason that the digestive organs do not readily adapt themselves to it—and the food lies there in its unchanged state, producing by heat and moisture, fermentation, irritation and inflammation.

Colic produced by oats is not as obstinate as that produced by corn. T. N. W.

Southern Planter.

ADDRESS OF THE HON. W. C. RIVES,

BEFORE THE ALBEMARLE AGRICULTURAL SOCIETY.

Seldom have we examined (says the Tennessee Agriculturist) an agricultural address of more interest than that delivered on the 29th of October, 1842, by the Hon. Mr. Rives of Virginia, and did our limits admit, we should be pleased to lay the whole document before our readers. A few extracts, however, we think, cannot fail benefitting the public, and we will hear him first on

AGRICULTURAL EDUCATION.

"A public endowment, under the patronage of the State, for instruction in the principles and practice of agriculture, is imperatively due to that great class of the community, which is immediately connected with the cultivation of the earth. We have, in great number, schools of law, schools of medicine, schools of general literature, but none of agriculture. Why is this so? The recent census shows that the number of persons engaged in agriculture is four times greater than the whole number of persons employed in commerce, manufactures, the learned professions and trades of every description, all put together. Does not this consideration of policy and justice, then, require the provision of some means of professional education, in an art to which so predominant and vital a portion of the industry and worth of the country is devoted? Is agriculture alone to be degraded into an empirical pursuit, which requires no liberal instruction? On the contrary, there is no other profession, I will venture to affirm, which demands, for its intelligent exercise, so wide a range of scientific knowledge. It embraces within its scope, by a direct and necessary dependence, the domain of chemistry, botany, vegetable physiology, geology, mineralogy, meteorology, zoology, mechanical philosophy, not to speak of the moral and political sciences which have so important a bearing, in many respects, upon some of its highest interests. To which of the *learned* professions, so called, I would ask, is so large a group of kindred sciences associated in such close and intimate relationship?

These considerations are making themselves daily more and more felt, and are arousing public attention, in every enlightened community, to the just claims of agricultural education. A professorship of agriculture has been since established in the universities of Edinburg and Dublin; and from the former has recently proceeded one of the most valuable works on the "elements of practical agriculture," ever published. If distinct professorships of agriculture have not yet been founded in the English universities, arrangements are in progress for establishing them; and in the mean time lectures of distinguished ability have been delivered on the subject by some of their learned professors, —among which it would be inexcusable not to mention particularly the lectures of Professor Daubeny of the University of Oxford. It is time that Virginia should acquit herself of the debt which every enlightened and especially every Republican commonwealth owes to this great primordial interest of society. We must have a professorship of agriculture in our University as a part of the general course of liberal studies, to furnish our young men, when they quit its walls, with a competent knowledge of the principles of a profession which so many of them embrace in after life. In addition to this, there should be established in connection with the University, a *special agricultural institute*, designed for those who might not wish or find it convenient to follow the general course of University studies, but whose object would be to acquire in shorter time or at less expense, the professional education of an instructed agriculturist, as well as the general accomplishments of an intelligent and useful citizen. In this department, theory and practice should go hand in hand; and for that purpose, a model and experimental farm should be attached to the institute to be conducted under the most skilful supervision and management, and to afford examples of the most improved methods of culture and fertilization.

Of such an institution, a perfect examplar, tested by forty years of successful experience, is presented to us in the admirable and celebrated establishment of Von Fellenberg at Hofwyl in Switzerland. I am spared the necessity of details in the developement of this suggestion, by simply referring to that well known establishment as a general model, admitting readily of modifications where a difference of circumstances may be supposed to require them. It was my good fortune during my residence in Europe, to visit this classic spot; and I can safely say, that I saw nothing in the palaces of Kings, in the museums of the fine arts, in the gorgeous displays of wealth and power on every hand, which impressed me with half the admiration I felt in contemplating the modest but noble establishment of the Swiss republican patriot and sage. Agriculture he chose as the basis of his enterprise; and by the happy combination, in the training of his pupils, of intellectual and bodily labor, mutually relieving and giving zest to each other, he has achieved those prodigies of moral and physical improvement, which have drawn upon his institution the earnest attention and applause of the civilized world. It has furnished to Continental Europe the best models of its agriculture, while it has sent forth into its various States and Kingdoms some of their most useful, virtuous and enlightened citizens. At the same time, the model farm of Hofwyl stands a proud refutation of all the stereotype satires, so frequently indulged, on scientific farming, as the accounts of the establishment, kept with minute mercantile exactness, disclose through a series of years, a nett profit of 8½ per cent upon the whole capital employed—a rate of profit with which, I venture to say, any of us *practical* farmers would be more than content.

Mr. R. is not only a friend to a better system of education, but he is likewise a pioneer in the improvement of lands. Hear him on the subject of

LIMING LANDS.

Being somewhat of a pioneer in the lime husbandry in this portion of the State, I feel myself called on, gentlemen, to give you the results of my experience. I have used about 12,000 bushels of it, (slaked measure,) from a quarry opened for the purpose on my own land, which has been spread over about 150 acres, at an average, therefore, of 90 bushels to the acre. Some accounts which I have read of its effects elsewhere, not expressed with the accuracy and discrimination so much to be desired in such communications, had led me to expect a decided effect upon the *growing* crop—by which I mean the crop, of either corn or wheat, immediately succeeding the application of lime. In this I was disappointed; but the discrepancy is probably accounted for by the fact that I have not hitherto used lime in combination with putrescent manures from the farm yard or the stable, while others have most probably done so, though that circumstance was noted in the communications to which I refer. My first disappointment however, in regard to the effects on the growing crop, was more than compensated by the marked, unequivocal and decided effect I have never failed to perceive from the lime *alone* in the *clover* succeeding the wheat crop—with which it has been my general practice to apply the lime at the time of seeding, harrowing in the lime and wheat at one and the same operation. The increased luxuriance of the clover has furnished, of course, conclusive evidence of the improvement of the land from the application of the lime, and has in its turn, enured to the still further amelioration of the soil. All my observations in regard to lime would lead me to the opinion that it is the most *permanent* of all manures, and to concur in the conclusion so forcibly stated by Dr. James Anderson, one of the most copious and able of all the British writers on agriculture, who in his most valuable "Essay on Lime" says "*that its effects on the soil will be felt, perhaps as long as the soil exists;*" and this conclusion he justifies by the mode of its action altering the nature and constitution of the soil itself, and enduing it with capacities and affinities which it never before possessed. My applications of lime have been almost entirely on a close gravelly loam, of a brownish or gray color; and the result of a single experiment on land of a different description would lead me to believe that it is not adapted to the red ferruginous clay soils of the sides and base of our southwest mountains. It is a proverb in England and Scotland that

"He that marls sand
Will soon buy land;
But he who marls clay
Throws all away."

The reason that Dr. Anderson suggests for the the comparative inefficiency of marl on clay soils is, that clay forms a large proportion of marl, and the addition of clay to clay, therefore, cannot be expected to produce so good an effect. The same reason would furnish a solution of the supposed want of adaptation of lime to the red clay soils of the south west mountains *proper*, and of its unquestionable efficiency on the adjacent gray loams, as a chemical analysis of the two soils has, I understand, disclosed the existence already of two per cent of lime in the former, and of hardly any sensible quantity whatever, in the latter.

Nothing can be more certain than the highly beneficial effects of lime as a manure, on a large majority of our soils, in which, according to an analysis, by Mr. Ruffin, of as many as sixteen different specimens taken from various and distant parts of the State, lime is very rarely ever found as an original and natural ingredient.—The important practical question then is, whether the expense of the application is justified by the benefits of the manure. This is a question which every person must determine for himself according to his particular position, and his own views of profit and loss. For myself, I will only say that I have always found the best application I could make of money derived from the land, was to return it back to the land in the shape of improvement. There is no investment of capital that can be more safe, and in ninety-nine out of a hundred cases, none half so profitable. If by laying out five dollars in manure on an acre of land you make it produce you 20 bushels of wheat worth a dollar a bushel, when it produced but five bushels before, and this product is renewed to you every four years in an ordinary rotation of crops, have you not secured an interest of one hundred per cent on the outlay you have made, and at the same time increased the value of your land four hundred per cent! And yet results such as these, extravagant as they may seem, and though we may be unconscious of them ourselves, are often achieved by a liberal and spirited system of improvement. The *passion* of us Virginia farmers is to acquire more land—not to make the land we already possess more productive. If a farmer should add yearly to his possessions a hundred acres of land, he would doubtless consider himself getting along very prosperously in the world. But if at no greater expense he can make a hundred acres of land twice or thrice as productive as they were before, is he not doing much better, with the great advantage of having a more compact surface on which to concentrate his labor and care.

The misfortune of our Virginia agriculture is that we have already too much land for the labor we can bring to cultivate it. As we are not likely to make a voluntary curtailment of the extent of our farms, the greatest practical reform that can be introduced into their management is to curtail the arable surface on each, and to lay down a larger portion of our lands to grass. Instead of wasting the energies of our soil by annually spreading over a wide surface

a superficial, negligent and teazing cultivation, yielding comparatively nothing, how much better would it be to cultivate one half or one third of the spaee we now do, to concentrate upon that all our resources of labor and improvement, and to leave the rest to recruit itself by the healing process of nature. Liebig has explained in a very ingenious and philosophical manner the process by which lands laid down to grass are constantly renewing and improving themselves, and has thus confirmed the deductions of our own observation by the demonstrations of science. Should any one doubt whether we should derive from the reduced surface, better cultivated, a product equal to that of the whole under adequate culture, let him recollect the instructive story told by old Columelia, in his De re rustica, of a Roman vine-dresser, who had a vine-yard and two daughters; when his eldest daughter was married, he gave her a third of the vineyard for a portion, and yet he had the same quantity of fruit as before; when his second daughter was married, he gave her the half of what remained, and still the produce of his vineyard was undiminished.

RUST IN WHEAT.

The following extracts from a correspondence between Mr. Pleasants, editor of the Farmers' Register, and Mr. Peyton, on this important subject, are highly interesting and deserve the most profound consideration of planters.

The following letter is published at the instance of the gentleman to whom it was addressed, the more willingly in consideration of his reply, and because the correspondence may lead to some further discussion of the important subject to which it relates. The rust is, beyond doubt, by far the most formidable drawback upon the wheat crop with which the farmer has to contend. At the moment when his hopes are highest, it spreads as a cloud over his fields, and disappoints him of the reward of his labors.—We would request our correspondents to examine into the causes of this disease, and if they know of any remedy or preventative, to communicate it for the general good. If our own views are correct, we should expect that the use of marl has had a happy effect in guarding against its ravages. Will some of our readers inform us on this point.—*Farmers' Register.*

—

Chesterfield County, Nov. 23, 1842.

William M. Peyton—Respected Friend—* * * By the way, while I have the pen in hand, is not Roanoke a limestone country? I should suppose your soils were destitute of calcareous matter, from the fact that you are equally subject to the rust in wheat as we are in lower Virginia. I infer at least that such is the fact, from thy letters in the Southern Planter.—As far as my observation extends, lime is an effectual preventive of the rust. Putrescent manures and clover lays, on the contrary, almost always induce it if the season be at all unfavorable at the critical period of ripening. The reason I take to be this: putrescent matter, by furnishing more food than the plant can elaborate, produces a state of plethora, which results in the extravasation of the sap at the season of greatest vigor. This indeed I understand to be thy theory. The tendency of lime is to check this redundancy of growth, by providing in some way the specific food of the plant. Whether this be done by enabling it to decompose carbonic acid with greater activity, or by furnishing it with silicate of lime, or by contributing to the developement and formation of the grain, rather than to an exuberant vegetation, cannot perhaps be determined. When I was in the great wheat growing district of western New York, some years ago, I saw fields of wheat that I was told would yield 25 or 30 bushels to the acre, which I could not have supposed, from any previous observation, would have produced more than ten. The soils of that region being of a diluvial formation, are so rich in calcareous matter, from the former attrition of the lime-rocks scattered over the country, that they frequently effervesce with acids. The stem had so little blade that it appeared almost naked. Plaster of Paris, which has been recommended as a protection against the rust, though it be lime in another form, does not contribute much to the formation of grain. Its tendency is eminently to increase the bulk of vegetable growth, and therefore, when it acts on wheat, to induce rust and mildew. To guard against the rust then, such application to the soil appears necessary as would afford specific nourishment to the seed. In every analysis of wheat there is found a portion of lime. There are also some manures that furnish the specific ingredients, but those only I believe which are concentrated in their energy. I have read nothing lately which sheds more light on the distinction I have attempted to draw, between manuring for the grain and manuring for the straw, than the detail of some experiments with guano by J. E. Teschemacher, of Boston, and contained in his address to the Horticultural Society. Some plants treated with guano, the balsam for instance, produced very inferior flowers; but not a flower missed bearing its seed vessel, and every seed vessel was filled with perfect seed; while other plants of the same species, and growing under the same circumstances, with the exception of the guano, had only a portion of the seeds perfect in each pod, though the flowers were very fine.

There is a neighborhood in Maryland which I occasionally visit, the inhabitants whereof form a little community of intelligent and industrious farmers, who mostly belong to the same society of which I am a member, namely, that of the Friends or Quakers. They do their own work; and when one works with his own hands, he is more likely to make both ends meet. They find it to their interest to haul lime from six to ten miles to apply to a soil by no means naturally fertile. The crops of wheat on their limed lands are invariably good, and but little affected by rust.

A few years ago, a friend of mine, in an adjoining county, planted an acre or two of ground in pumpkins. The vines were so much infested with bugs that he sprinkled caustic lime over the leaves for the purpose of destroying them.—In the fall the lot was seeded to wheat, and at the ensuing harvest the locality of every hill was conspicuously visible. In each spot where the lime had been applied, the straw was bright and of a golden color, without the least appearance of rust; while in every other part the wheat was completely ruined. If it is not too late in the season, I would suggest the trial of a small piece of ground with lime or ashes, if it was no more than a few yards square. Ashes would be as beneficial as lime, for they afford potash.

With great respect,

T. S. Pleasants.

—

Big Lick, Roanoke, Nov. 27, 1842.

* * * I turn now to the main body of your letter, which contains suggestions of the utmost interest, and which, if correct, solves a long disputed problem, while it opens the prospect of incalculable benefits to the farmer. As there is nothing connected with the wheat crop which effects its successful culture so seriously as its liability to rust, I have felt disposed to throw into the common stock my mite of observation and experience, in the hope that others would pursue the same course, and that in the end some useful result might be attained by a comparison of the different views. My own notions, as developed in the different publications alluded to by you, have been that it results from a plethora, induced by excessive vegetation. That whilst some modes of cultivation, and especially the habit of applying the strong, stimulating manures of the stable and farm pen, would augment the tendency to rust, and other modes would partially ward it off, no skill could avert it entirely in some seasons. In my essay of July, in the Southern Planter, I say that rust never appears until the wheat has attained its full growth, and when there is nothing left for the leaves and stem to perform but the elaboration of the juices for perfecting the seed. When plants have reached this point, every physiologist knows that they require no further extraneous aid in the formation of the seed. The ovary has performed its office, fructification has taken place; and the gradual concentration of the juices of the leaves, stem and roots in the seed, producing the death of the former, is all that is required. Before attaining this state, excessive vegetation only produces excessive growth; but when the plant is fully developed, and nothing more required for the maturation of the seed but a slow, gradual and regular supply of duly elaborated sap, if there should then happen a warm, damp spell of weather, a succession of sunshine and showes, an inordinate flow of sap is at once produced, which destroys the consistency which is then so necessary to the grain, and you distend the vessels to such a degree, that they burst of their repletion, and exude upon the surface.—Should this occur when the wheat is in the milk state, it is destructive of the grain, which perishes for the want of proper nourishment.

In these and other views of the same essay, the very sensible editor of the American Farmer concers, so far as the nature and causes of rust are concerned but dissents *qualifiedly* from the conclusion to which "my premises and reasoning would lead." In this you and he seem to agree, though you reach the same point by contrary roads.

The editor of the Farmer, after wisely substituting bland vegetable manures for the strong putrescent manures of the barn-yard, suggests the application of gypsum, as an auxiliary agent in preventicg the too rapid decay of the vegetable matter. He is led to this suggestion by the present received explanation of the action of this mineral. Liebig says, as quoted by him, "that the action of gypsum really consists in its giving a *fixed* condition to the *nitrogen* or *ammonia*, (food of plants) which is brought into the soil, and which is indispensable for the nutrition of plants." He adds further, that the decomposition of gypsum by carbonate of ammonia does not take place instantaneously; on the contrary, it proceeds very gradually, and this explains why the action of gypsum lasts for several years. From these quotations, the editor thinks it fairly inferable that the plaster would act as a retarding principle, and thus enable them to regulate the supply of nutriment to the crop.—My letter, which was *partially* published in the November number of the Southern Planter, was intended to give some experiments in opposition to the editor's theory. Without presuming to question the soundness of Liebeg's views, but on the contrary adopting them unqualifiedly, I thought they might by reconciled with my own in this way. Gypsum requires to dissolve it from 300 to 500 parts of water, and when dissolved, it decomposes very slowly under the action of carbonate of ammonia; of course this slow and gradual process is calculated to fix the ammonia in the soil. But then, on the other hand, plaster attracts a vast amount of floating nitrogen or ammonia from the atmosphere, thus increasing the agent of decomposition (carbonate of ammonia) greatly. A large portion of the peculiar food of plants would thus be disengaged, so that under the action of plaster you would have a larger amount of ammonia fixed in the soil, and a larger amount appropriated by the plant, than you would have if it were not employed. This explanation accords with our experience of the influence of this manure, the "tendency of which" as you say, "is eminently to increase the bulk of vegetable growth, and therefore, when applied, to induce rust and mildew."

Concurring with me as you do thus far, you here fall back upon the position of the American Farmer, and suggest lime as an effectual preventive of the disease. To answer this great end, you suggest that the remedy should be such a one as would afford specific nourishment to the seed. Every analysis of wheat exhibits lime

and phosphate of potash among its constituents. This would bring us back again to the plaster of Paris, which is a sulphate of lime; but experience has shown, as you justly say, that this does not contribute much to the formation of seed, but acts more especially on the stalk and leaves. Lime, however, in other forms, both calcined and as it exists in the highly concentrated manure which is termed guano, has, you think, the desired effect on the seed. The experiment of J. L. Teschemacher, of Boston, is certainly very striking; while your own experience of the influence of calcareous applications in Maryland and other localities does certainly carry with them a force and weight which it is difficult to resist. Previous to the reception of your letter, I had seen it stated with great confidence in the Dollar Farmer of Kentucky, that ashes were an infallible protection against rust; and I have instituted a set of experiments upon wheat sown this fall to test it. I will now add some experiments with lime, and give you the results of both next summer.

Roanoke county is a limestone soil, the best portion of it, within memory of its oldest inhabitants, having been a prairie, which, according to Mr. Ruffin's theory, would show that our soil is strongly impregnated with lime, and which, with your theory added, should exempt us from the rust. We however have it, though I think we are not peculiarly liable to it. Kentucky, however, which is the purest calcareous soil I have ever seen, does seem to be peculiarly subject to this disease; so much so that her farmers have, to a very great extent, abandoned its cultivation as a staple.

I hope, sir, that you will continue to investigate this truly important question, with all the industry and research of which you are capable. Keep public attention alive to it until some useful and satisfactory result is reached, and you will have conferred a lasting benefit upon the community, which will entitle you to their warmest gratitude.

Wm. M. Peyton, Roanoke.

Recipe for making Good Bread.—James Roche, long celebrated in Baltimore, as a baker of excellent bread, having retired from business, has furnished the Baltimore American with the following recipe for making good bread, with a request that it should be published for the information of the public:

"Take an earthen vessel, larger at the top than the bottom, and in it put one pint of milk-warm water, one and a half pounds of flour, and half a pint of malt yeast; mix them well together, and set it away, (in winter it should be in a warm place,) until it rises and falls again, which will be in from three to five hours, (it may be set at night if wanted in the morning;) then put two large spoonfuls of salt into two quarts of water, and mix it well with the above rising; then put in about nine pounds of flour, and work your dough well, and set it by until it becomes light? Then make it out in loaves. New flour requires one-fourth more salt than old and dry flour. The water also should be tempered according to the weather; in spring and fall it should only be milk-warm; in hot weather, cold; and in winter, warm."

Foot-Rot in Sheep.—Mr. R. North, Jr., in a note to the Editors of the Cultivator, says, after trying several recipes for the foot-rot in sheep, which he had seen recommended in their paper, to very little or no purpose, he discovered by mere accident a cheap and sure cure, without much trouble or injury to the sheep, viz: "Take a few bushels of lime, and put it near some place over which the sheep have to pass, say the bars; and as it is natural for sheep to jump, take notice where they alight, and place the lime there, about three inches deep. This did effectually cure my flock in about one week. The lime should be fresh and slacked, and not less than three inches deep; if deeper, it might take the hair off the leg above the hoof."

IMMENSE SUCCESSIVE CROPS OF WHEAT—MODE OF MANURING, &c.

In our paper of the 21st ult. we gave an extract from an essay of S. H. Black, Esq., in which he stated that Adam Whann, Esq., of Elkton, Maryland, had raised wheat on a ten acre lot for four successive years; that the product had averaged 400 bushels per year, or 40 bushels to the acre, and that the lot was then in wheat, making the fifth consecutive year. Appended to that extract, we made such comments as the extraordinary nature of the case appeared to justify, and respectfully called upon the venerable owner of the lot to favor the public with answers to certain queries which we took the liberty of submitting to him. To those queries Mr. Whann has made a prompt and satisfactory response, as will appear by the annexed communication.

There are two features about Mr. Whann's culture, that go to astound us. The first is, that such heavy crops should, without change, be grown for five successive years on the same land; and that such success should have attended his wheat crop after being manured with stable manure; for *that*, with the exception of the burning of the stubble one year, was the only manure which his lot received during the whole period it was in wheat. The growing of successive crops of the same grain upon the same land, and the manuring of wheat with stable manure, are both opposed to the approved theory of rotation of crops, and he who should undertake to do either, at this day, would be considered a bold experimenter, if not a daring innovator. In England, as well as in this country, it is considered that the rust, in a majority of cases, will attack any wheat thus manured, and yet in the case of Mr. Whann, although, in some instances, his neighbors' wheat was rusted, his escaped unscathed. It is not our intention to attempt to determine to what cause this immense product is to be ascribed, and for the very obvious reason that we feel uncqual to such task; but it may be profitable to note the facts as presented, so as to elicit inquiry by experienced wheat growers. And with that object we will endeavor to present the results in such form as to be the most striking to the eye of the reader.

In the first place it may be well to remark, that the lot had been cleared for many years, and had been a considerable time in clover and timothy.

The following will show the course of treatment and crops:

First year—Corn; ploughed and harrowed; manured with clover ley; product of the ten-acre lot, 850 bushels; product per acre, 85 bushels. Second year—Barley; ploughed and harrowed; without manure; product of the ten-acre lot, 350 bushels; product per acre, 35 bushels. Third year—Wheat; ploughed and harrowed twice; manured with stable manure; product of the ten-acre lot, 422 bushels; product per acre, 42 1-20 bushels. Fourth year—Wheat; ploughed and harrowed; manured with stable manure; product of the ten-acre lot, 400 bushels; product per acre, 40 bush. Fifth year—Wheat; ploughed and harrowed; manured with stable manure and burned stubble; product of the ten-acre lot, 350 bushels; product per acre, 35 bushels. Sixth year—Wheat; ploughed and harrowed; manured with stable manure; product of the ten-acre lot, 400 bushels; product per acre, 40. Seventh year—Wheat; ploughed and harrowed; manured lightly with stable manure; product of the ten-acre lot, 300 bushels; product per acre, 30 bushels.

By examining the above, we find that this lot, out of a course of culture of seven years, was five years in wheat; that during each of those latter years, the ground was enriched with stable manure, and that, notwithstanding the application of this heating substance, it continued to yield immense crops, making an average acreable product of more than 37 bushels of merchantable wheat; that the falling off in the last of the five years, is accounted for by Mr. Whann, who ascribes it to his sowing white wheat instead of red, on one half of it. The half in white only yielding 100 bushels, while that in red produced 200, being equal to any of the preceding years but the first, so that in fact there could not be said to have been any falling off in product, that was not produced by an error in substituting one kind of wheat for another. Let us point out the system pursued by Mr. Whann:

He ploughed once and harrowed twice.

He sowed early, viz: on the 15th of September in each year.

He sowed two bushels to the acre.

He changed his seed each year.

He manured with stable manure and lime—and

The kind of wheat which he found best was the red chaff.

We think it was by his early sowing, that he was enabled to escape the rust, and may it not have been the vigorous growth of the wheat plants, superinduced by the stable manure, that induced them to resist the fly. We merely suggest this opinion, and will mention that Earl Stimson, of Saratoga county, New York, always makes his wheat crop the first in rotation, and manures it both with barn-yard manure and leached ashes, in the proportion of five loads of the former to three of the latter. His crops of wheat average from 30 to 40 bushels to the acre, in fields of 50 and 60 acres. We allude to this latter fact with the view of letting our readers see that Mr. Whann's case is not an isolated one, and that he does not stand solitary and alone in the successful application of animal manure to wheat.

With these remarks we will call attention to the subjoined letter from our venerable and respected correspondent:

Elkton, January 6, 1843.

Dear Sir—I observe in your paper of the 21st ult., a request that I should give you some information respecting five successive crops of wheat grown on a ten-acre lot which formerly belonged to me at this place. The lot was clear of timber as long as I had any knowledge, except two or three black walnut trees. The soil is a light sandy loam mould; it had been in clover and timothy for some years, then put it in corn, and it produced 850 bushels of good sound corn, then ploughed the next spring, and 20 bushels of barley sowed, produced 350 bushels. That fall manured over with stable manure, ploughed once, and 20 bushels of good red chaff wheat sowed and harrowed each way. The produce was 422 bushels wheat, weighing 61 lbs. to the bushel; the second year manured over with stable manure and ploughed once as before, limed and harrowed in, produce 400 bushels. Third year being a very dry season, ploughed a few furrows round the lot and set fire to the stubble and turned it into the earth; then gave it a light coat of stable manure ploughed once, limed and harrowed as before; produce 350 bushels.—Fourth year covered over with stable manure, ploughed once and harrowed as before, produce 400 bushels. Fifth year covered over lightly with stable manure, ploughed once, limed and harrowed in as before, produce 300 bushels. I sowed my wheat about the 15th September, never ploughed but once a year, and harrowed in both ways, changing my seed every year. It was not disturbed by any insect during that time. Some of my neighbors complained of the fly and rust affecting their crops, but mine was not affected with either. I attribute the small crop of the fifth year to my having seeded one-half the lot with white wheat—the produce of that half was only 100 bushels.

Respectfully your friend,

Adam Whann.

Coffee, from sweet potatoes, is warmly recommended. The potatoes are pared, sliced, roasted, ground and steeped, like the coffee berry. It is said to be very palatable, has the flavor of cocoa, and requires little sugar.—*Ex. paper.*

What an age and a country this, when and where people may "luxuriate" on sweet potato coffee and cornstalk sugar—*Boston Cultivator.*

WEDNESDAY, MARCH 22, 1843.

☞ We appeal to every subscriber to the "Southern Cultivator" to make an earnest and zealous effort to extend its circulation.—There should be from 50 to 200 subscribers in every county in the State—and if the friends of the cause will make the effort, they can be readily obtained. It is a matter of interest to every reader of the paper, for in proportion as the circulation is extended will its usefulness be felt and appreciated, and its capacity to do good be greatly facilitated.

CORN-STALK SUGAR.

The importance of this subject to the planters of Georgia and the South generally, where corn grows so luxuriantly, should commend the article copied into another part of this paper, from the report of the Commissioner of the Patent Office, to the careful perusal of every reader.—It is particularly a subject of deep interest to the cotton growing States, as affording another, and perhaps profitable, field for the employment of a portion of that labor now bestowed on the culture of our great staple—the price of which is so low as to demand that a portion of the labor heretofore employed in its production, should be diverted to the growing or manufacturing of other articles of consumption, to which we have heretofore paid no attention. We expect not that any portion of our planters will suddenly embark extensively into the making of corn-stalk sugar—such a course would not be dictated by prudence or a sound discretion—but we do anticipate that the result of the experiments heretofore made, will induce many to make the experiment on a small scale, and at a very limited expense, in order to test its practicability in this climate, which we doubt not will be found much more congenial than the Northern, Middle or Western States, where success, to some extent, has crowned the labors of those who have embarked in it. The process is indeed simple, and may be tested in a small way at a very trifling expense, and we do hope some of the more enterprising of our planters may be induced to make a trial.

Brine.—One of our citizens, a grocer, informs us that he has, for a few years past, been in the habit of emptying the brine from his pork and fish barrels on his asparagus bed; and he thinks none of his neighbors have better asparagus than he. The effect of the brine is entirely to destroy the weeds, while it makes his plants much more thrifty. And why is not this reasonable? Asparagus is known to be a marine plant, and is found in abundance in many places along the shore of the ocean.

Ed. Farmer's Gazette.

RUST IN WHEAT.

Under this head, in another part of this number, the reader will find a very interesting correspondence between Mr. Pleasants and Mr. Peyton, of Virginia, to which we invite attention. There is, perhaps, no section of the Union where the wheat crop sustains a greater injury, in proportion to the quantity cultivated, from rust than the South, and it is therefore of the highest moment, to all who attempt to cultivate this important bread stuff, to understand the causes, and, if possible, apply the remedy. Such indeed has been the extent of its ravages for a series of years in some sections of the country, that many planters have ceased to cultivate wheat at all, and rely exclusively upon the importation of their flour from abroad. Every possible effort should therefore be made to discover the cause of the disease, and, if possible, remove it—for the importation of flour alone into the cotton growing States is no inconsiderable item, and if by any means the culture of wheat can be so improved as to enable us only to supply the home demand, it will be an important point gained, the advantages of which cannot be readily ascertained.

THE POTATO.

It is, perhaps, not generally known to the subscribers of the Farmers' Cabinet, that in the potatoe there are two parts, which, if separated and planted at the same time, one will produce tubers fit for the table eight or ten days earlier than the other. This fact has fallen under my own observation, and is the plan I now pursue in order to obtain an early supply for my table, fine and very mealy. The apex or small end of the potato, which is generally full of eyes, is that part that produces the earliest—the middle or body of the potato produces later, and always large ones. The butt or navel end is worthless, except for feeding stock, and, if planted, produces very indifferent small ones, and often none at all, the eyes, if any, being imperfectly formed. The potato being cut two weeks before planting, and spread on a floor, that the wounds may heal, separating the small ends from the middle, then cutting off the navel or butt, the body or middle of the potato is then divided into two pieces lengthwise, taking care to have always the largest and finest selected, being convinced that if none but large potatoes are planted, large ones will be again produced—small things produce small things again, and therefore no small potatoes should be planted; this practice is too prevalent, and may account for the many varieties and small potatoes met with in our markets. Who would not prefer a large mealy potato to a small one, that will take hours to boil soft, and then may only be fit to feed the cattle with?

For several years past I have adopted the plan of putting potatoes into the ground late in the fall, covering them with manure, sometimes with tanner's waste bark, and always have succeeded in raising a fine early crop. Last fall I had taken up some as fine and large Mercer potatoes as any one could wish; they were covered with tan six inches thick the preceding fall; many weighed sixteen ounces. No particular care or attention was bestowed upon them thro' the summer, the tan not permitting any weeds to trouble them, or to draw out the nourishment from the earth, they had therefore all the benefit of the soil, kept moist and clean by the tan, for tan will keep the ground moist and clean and in an improved state in the driest season. I have found the great advantage of it to my asparagus and strawberry beds, which are annually covered with it.

The potato I consider so valuable and indispensable a vegetable, and having never seen a suggestion in print of separating the potato and planting each by itself, that I have been induced to send you this imperfect and hastily drawn up communication. Perhaps you may think it worthy a place in the Farmers' Cabinet, and if so, should be pleased to hear that some of its patrons will try the experiment of planting separately each part of the tuber, believing that the potato may be much improved by a due regard to the above suggestions. J. F. H.

Farmers' Cabinet.

BLACKSMITH'S WORK.

As many of our farmers have blacksmith's shops of their own, the following directions for working steel and making edged tools, plain and simple as they are, may be of great value to them if carefully enjoined upon their smiths, who are frequently great bunglers in this kind of work.—*Southern Planter.*

"Working Cast Steel.—We have recently obtained information on this subject from the most skilful and celebrated workman in the United States, Capt. J. Hill, of Billerica, Massachusetts. We were a little surprised to learn the difference in the management of cast steel, from that of the German. There is something yet remaining mysterious with regard to the nature and management of this article, which no cyclopedia or other vehicle of intelligence have as yet developed. The process of manufacturing cast steel, it is not our purpose at present to describe; but it is evidently composed of refined iron and carbon in very nice proportions. In the process of shaping it into cutting blades and other articles, it is heated and hammered in the manner of other steel: when tempered for this purpose, it is first heated to a full cherry red, and plunged into water till cold. It may then be held over a moderate charcoal fire, until the color of any part which has been filed or made bright after hardening, changes to a reddish orange color. This is the temper for cutting tools: but if a spring temper is required, it is heated over the charcoal till the color approaches a blue; or rather, blue inclined to red. In either case when the steel is brought to show these colors, it is to be plunged in oil—common lamp or linseed oil—which will not affect the color. If the steel is to be rendered soft for turning or cutting, it must be heated to a full red, and left to cool in partially ignited charcoal; in this way it may be made so soft as to be cut or turned into shape as easily as copper, or even common pewter. But the most curious and peculiar process is that of welding. In welding iron, a white heat is indispensable, as every body knows: but not so with cast steel. When the steel is to be welded to iron, neither are to be heated above a full cherry red. The two parts are to be previously lashed or *griped* together, and in that condition heated: they have then only to be immersed in calcined borax; or to have the prepared borax (borate of soda) sprinkled over the joint, and are ready to adhere by being hammered together. The borax for this purpose is to be prepared by being previously heated to a full red, and kept heated till it becomes a soft powder like flour. What the chemical effect of the calcined borax on the metalic surfaces is, is not perfectly understood, farther than that its affinity for oxygen is such as to deprive the jointed surfaces of any portion of oxygen which might prevent a ready union of the surfaces. When small pieces of steel are to be welded, they are to be heated to the full cherry red, and immersed in the calcined borax, and are then to be hammered together. The most extraordinary point in the process is the fact; that if the steel is but a little overheated, it will immediately crack into fragments; but by a shifted process, and with the use of borax, the cracks and defects may be healed and rendered sound and solid. We have witnessed the fact, that by a judicious management, a fine tempered cutting edge of cast steel may be bent, warped and hammered, and its shape materially changed, without breaking, or affecting the temper. More may be said on this

subject in a future number; but we close for the present with the remark that even Anderson & Co., the celebrated manufacturers of cast steel, are evidently unacquainted with all the merits of its peculiar properties.—*Amer. Mechanic.*

TO MAKE PERMANENT MARKING INK.

Take six and a quarter cents worth of lunar caustic, and, having put it in an ounce vial filled with vinegar, cork it tight and hang it in the sun. In a couple of days, it will be fit for use.

To make the preparation for the above, take a lump of pearlash the size of a chesnut and dissolve it in a gill of rain-water.

The part of the muslin which is to be written upon is to be wet with the preparation, and dried and glazed with a warm flat-iron: immediately after which it is ready for marking.

A little vinegar, in which a rusty nail has remained for a few days, makes a mark on linen which is not easily obliterated---forming what is commonly called iron-mould.

Louisville Journal.

JOSIAH QUINCY, President of Harvard College, has one of the finest farms in the vicinity of Boston. It is extensive and surrounded by a flourishing hawthorn hedge, but there is not an interior fence on the premises; the whole presents a single field, devoted to all the various purposes of agriculture. No part of it is allotted to pasture, properly speaking, as his cattle are fed in their stalls and never suffered to roam over the fields—and the advantages of his system are thus given: Formerly there were seven miles of interior fences to be kept in repair, but by keeping his cattle up the whole of this expense is saved. Formerly sixty acres of this farm were devoted to pasture; but now a greater number of cattle by one-third are kept on the products of twenty acres, and the cattle are in the best condition.

The saving by these means is enormous, and the immense advantages arising from it are too apparent to need to be dwelt upon. During the summer the cattle are fed upon grass, green oats or barley, cut the day before and suffered to wilt in the sun, but the manure which is thus saved will more than pay the extra expense and trouble. The farm is most highly cultivated, and every kind of grain and vegetable has a place.

TO CURE SHEEP SKINS WITH THE WOOL ON.—Take a spoonful of alum and two of saltpetre; pulverize and mix well together, then sprinkle the powder on the flesh side of the skin, and lay the two flesh sides together, leaving the wool outside. Then fold up the whole skin as tight as you can and hang in a dry place; in two or three days, as soon as dry, take down and scrape with a blunt knife till clean and suple. This completes the process, and makes you a most excellent saddle cover. If when you kill your mutton you treat the skins in this way, you can get more for them from the saddler than you can for the wool and skin separately disposed of otherwise.

N. B. Other skins which you desire to cure with the fur and hair on, may be treated in the same way.—*Selected.*

NEW METHOD OF GROWING ASPARAGUS.—The editor of the Horticultural Magazine, recommends a trial of the following method of growing asparagus, which is practiced at Nice, and of which a high account is given in the London Gardeners' Chronicle. Take a quart wine bottle, invert it over the head of a stalk of asparagus just rising from the ground, and secure it by three sticks so that it cannot be knocked over. If left in this state, the asparagus will grow up into the interior of the bottle, and, being stimulated by the unusual heat and moisture it is then exposed to, will speedily fill it. As soon as this has taken place, the bottle must be broken, and the asparagus removed, when it will be found to have formed a thick head of tender delicate shoots, all eatable, and as compact as a cauliflower.

AGRICULTURAL FACTS.

Let every farmer and gardner whose eye rests on the heading of this article, consider himself most earnestly entreated by us to send us "facts," or even a single "fact" which may come to his knowledge, in his practice in his rural business. No matter how unimportant a "single fact" of this kind may appear to the narrator, it may become of incalculable utility to the community. No matter in how rude a form it may come to us, we can so polish the rough gem, that it may come out a diamond in value. What could not be effected for the common agricultural interest, if the farmers of the West would only send us the unstudied results of their experience, in every particular instance of an apparently new discovery? If we could only get them into this most valuable habit, each would be reaping the benefit of the other's labors, and be adding to the general store-house of information. We will leave it to their choice whether to sign their names or initials only, to their communications, but the names seem the most honest way. Come good friends of a common cause, send in your "facts," or but one "fact," in any manner you please, connected with the cultivation of the grains, the grasses, farm stock, implements of husbandry, manures and the manner of applying them, and the rest of the innumerable points of interest relating to the great fundamental building of man's wants and happiness in this physical department of his condition.—*West. Farmer.*

OXFORD SAUSAGES.

The following recipe for making the celebrated Oxford Sausages, so much desired by the lovers of good eating in England, is from a late English publication:

INGREDIENTS.—One pound and a half of pig meat cut from the griskins without any skin, and a half a pound of veal. One pound and a half of beef suet, the yolks and whites of five eggs. A dessert spoonful of sifted sage, after being well dried. Pepper and salt to taste.

TO MAKE THE ABOVE INTO SAUSAGES.—Chop the meat into small pieces and then pound it together in a marble mortar till it is short and tender. Chop the suet very fine, and when the eggs are well beaten together, after the white specks are taken out, pour the liquid over the pounded meat and chopped suet, well kneading it together with a clean hand, throwing in the sifted sage, and pepper and salt from a coarsish pepper box during the operation, so as to let them impregnate the whole mass without being predominant in any part of it.

Press the whole when well mixed together into a wide mouthed jar, and keep it from the air in a cold place.

Roll the sausages on a flour board and use very little grease in frying them, as they will be fat enough to fry themselves with the aid of a frying pan.

DISTEMPER IN DOGS.—We published in a late number a remedy for this disease, copied from the Southern Planter. We have often succeeded in curing the disease, by administering doses of salt as recommended therein; we have, however, whenever we discovered a constipation of the bowels to supervene, given every other day boluses of castile soap, with the very best effects. If castile soap cannot be had, brown soap will answer equally well, the object being action upon the intestinal viscera. In obstinate cases, where the discharge from the nostrils is obstructed, or the cough heavy and tight, we have always found the patient greatly relieved by introducing a seton in the loose skin just back of the head; which operation is performed by threading a coarse darning needle with a double thread of coarse yarn, and running it through the skin and confining it by a tie. The thread must be moved every morning to keep up irritation, and encourage a discharge of the viscid matter, which should be daily washed off with a little warm water and soap.

American Farmer.

FOUNDER.---I lately had occasion to try a recipe published in your valuable periodical, with the most complete success. Not long since, my barouche horse being badly foundered, I had holes dug in the ground, nearly knee deep, and filled with water; the water was then heated with hot stones, and the horse led into it, where he was kept for two or three hours. At the same time, I had him well bathed up to his shoulders and hips with hot water, and then rubbed dry. On the second morning, he started on a journey of two hundred miles, which he performed without any apparent inconvenience at all.

Your obedient servant, W. H. DUPUY.

Southern Planter.

BEESWAX.---The neatest way, says the Farmer's Cabinet, to separate beeswax from the comb, is, to tie it up in a linen or woollen cloth or bag, with a pebble or two to keep it from floating; place it in a kettle of cold water, which hang over the fire; as the water heats, the wax melts and rises to the surface, while all the impurities remain in the bag.

AUGUSTA MARKET.

WEDNESDAY A. M., March 22.

Cotton—Since our last report the weather has been so unfavorable for business that but few sales have been made, and the market cannot be said to have fairly settled down since the accounts per Great Western from Liverpool.—The prices range from 3¾ to 6 cents as extremes, while the great majority of the sales are from 4½ to 5¼ cents.

Trade—The unfavorable character of the weather has also operated upon the general business, and but a limited amount of trade has engaged dealers for the past week. To-day, however, we have a bright, clear sky, with a bracing west wind, and as our merchants in every branch of trade are being replenished daily with seasonable goods, they hope for a cheering spring trade.

Exchange—The market continues abundantly supplied with sight exchange at par on all points north and east of us. Central money is stationary at 25 to 30 per cent discount—principal sales 27. Alabama money is at a discount of 20 to 25 per cent. The amount of other depreciated money offering is so small that there are no fixed rates.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., MARCH 29, 1843. NO. 4.

CORN STALK SUGAR.

Numerous experiments have been tried in various parts of the country, the past year, with respect to obtaining sugar from the corn stalk.

I could, indeed, hardly be expected that persons entering into it without much knowledge of the process of manufacture, and, in many cases, never having been furnished with any plan on which to conduct it, and possessing no requisite marhinery, and before the difficulties attending its granulation had been removed, would be successful in their efforts. Yet the results have every where been so satisfactory, that though but little sugar has been made, no one person from whom we have heard, expresses a doubt of its entire practicability, or the least discouragement. On the contrary, they, one and all, confidently assert that the product will yet become a great staple in our country. An excellent molasses, or syrup, has usually been obtained; and were this the only thing secured, yet, in this point of view, it would doubtless prove a great desideratum.

Mr. Webb of Wilmington, Delaware, to whom the country is so particularly indebted for introducing this discovery to notice, and for his perseverance in demonstrating its practicability, made a definite experiment on a certain amount of land, sown as he had before recommended. Speaking of his former views, he says: "These anticipations have been more and *more confirmed by every succeeding step in the investigation.*"—He says further: "There was no deficiency in the *corn;* it was entirely in our mode of treating it; and, after all, the failure was only in crystalization." It appears that the corn was fully ripe before the least preparation had been made for manufacturing it; and, after this, delays were occasioned by breakages, incident to new machinery, by which the progress was so hindered that a considerable part of the crop was killed by the frost before it could be ground. He goes on to observe that the greatest part of the sugar he obtained was from this frost-killed corn, and says: "This fact is important, as it shows the superiority of the corn over the cane." In this point it would seem he is mistaken, according to the account above given of the cane crop of Louisiana. He further says: "We obtained 50 gallons of syrup, which (being boiled to the density of sugar,) was much richer and better than the best sugar house molasses; part of it was sold at $1 per gallon. We also had 10 gallons of syrup evaporated in broad shallow vessels; this crystalized readily, and made good sugar." Again: "Besides the products above mentioned, we obtained from the acre about 40 gallons of vinegar. The fodder was equal in value to two tons of hay; and there were 20 cart loads of stalks after passing the mill. One-fourth of the crop was lost in consequence of being prostrated by a storm late in the season, and another fourth from the stalk being imperfectly pressed. Considering every thing, the result is satisfactory." A fair review of the progress of this experiment fully justifies his language: "I do not think that any manufacture ever promised better, in the early stages of its introduction." In the Farmers' Cabinet for January, 1843, a correspondent of that journal, whose opinion seems entitled to consideration, remarks: "Few persons would be apt to calculate the expense attendant on even a small experiment in the making of sugar, whether from the cane, the beet, or the corn stalk; all who know any thing about it, however, are aware of the fact that the process, even from the first, is proverbially laborious, careful and expensive."

"Mr. Webb's apparatus cost him about $300. I should rather add $1000 to that sum. In my own opinion, the cause of the failure in the attempts to make sugar from the beet has arisen from the single circumstance of its never having been taken up on a sufficiently extensive scale. In France, there is no difficulty or delay experienced; but there the machinery is equal to the labor required." The writer also refers to Mr. T. Morgan, of Louisiana, and says "that, according to his experience, the juice of the cornstalk, as stated by the saccharometer, is *two tenths* stronger than the juice of the Louisiana sugar cane—a circumstance accounted for by the fact that the cane does not fully ripen in Louisiana, so that the juice is incipient."

On the other hand, the corn ripens perfectly, and then affords a juice properly corrected and matured, and hence defecation of it is remarkably easy. He further says: "I have been informed that Mr. Morgan was so well satisfied of the cultivation of the cornstalk for the purpose of making sugar, that he, the last year, gave orders for the growth of a certain breadth on his sugar plantation in Louisiana, the past summer, so as to give him a full boiling of juice for his vacuum pan, that the trial might be made on a scale sufficient to produce actual results, by which to calculate, in a pecuniary point of view, the real value of the cornstalk in the manufacturing of sugar, but that his intentions were frustrated, levelled to the dust, by a storm, which prostrated the corn, and entirely ruined his prospects." Speaking of some samples of sugar manufactured by Mr. Webb, he says: "It has been objected, that the grains are not so large and fully developed; it is only a wonder that any grains at all should be made to appear, from the manner in which the granulating process had been compelled to be carried on. Mr. Morgan, with his 10,000 gallons of liquor, at 45°, would soon be able to give a better account of the matter."

Mr. Blake of Indianapolis, in Indiana, also tried an experiment on a large scale; but not having as much previous knowledge of the process as Mr. Webb had, did not succeed in obtaining sugar. He says that he made in all, out of about 4½ acres, about 270 or 280 gallons thick syrup; 25 gallons of the juice ma le 4 gallons of the syrup; and he is well assured that he left in the ground corn one-third of the juice. His corn was planted four feet wide, and drilled one way. He planted about six acres, but a portion of it was prostrated by a storm, and so was not used. He found that wooden cogs and journals for the mill would not answer, and recommends iron-bound and iron-plated, and metal cogs and journals. He had no previous knowledge of sugar-making, of any kind, and of course had to encounter all the difficulties of a learner.—For boiling, he used common 15 gallon iron kettles. The great difficulty he found was in arriving at the graining point in boiling. His plan was to boil the juice of the cornstalk, as soon as the scum was removed, down to a strong syrup, and then put it into a cooler, or large tub, having two or three inch holes, one in a level with the bottom, the others an inch and a half from the bottom, and let it remain to the next day, and then boil it down to the graining point. He says also, "my main object in trying the experiment was to ascertain whether cornstalk contained saccharine sufficient to make it an object to cultivate it hereafter, as one of the great staples of our State. On this point, I am satisfied that, in a few years, it will become an article of export and of great value to the west."—"My molasses is esteemed by all who taste it, to be superior to New Orleans." "From experiments I made when I had got my mill to work well, I could grind 300 gallons of juice in about 18 hours' work, with two horses, allowing one hour for each horse at a time; two boys could attend the mill with ease."

"From the best estimate I can make of the cost per acre, in removing the ears, blading, topping and cutting, hauling, grinding and boiling, &c., it was between $12 and $15. Of course, it would have cost much less, if I had been as well organized as I could be, were I to carry on the business upon the same scale hereafter; boys can do most of the work." He also expresses his full intention to go into the business with a view to permanency and profit.

Others also in Indiana, tried the experiment with various success, and by a communication from Mr. Plummer, of Richmond, in that State, it appears that, in all cases, the success equalled expectations as to the quantity per average acre; but the quality was not so fine as expected, and it was supposed some added more cream of lime than was necessary. The sugar, however, proved equal to about second quality New Orleans. He also remarks, that they found wooden rollers would not answer as well, as they were liable to cut in ridges, and thus much of the saccharine matter was lost. He further suggests, that, by planting the corn some days apart from each other, one mill might serve a number of persons, and thus the expense be lessened. The farmers there, he adds, as an evidence of their confidence, do not expect to open their sugar trees again.

The conclusion is expressed by several, that from 600 to 1000 pounds of sugar may easily be procured from an acre.

Another person speaks of obtaining half a gallon of syrup from a bushel and a half of crushed stalks. Mr. Goodrich, of Terre Haute, in Indiana, is also stated to have produced from eight gallons of juice two gallons of molasses, pronounced by competent judges equal to the best sugar-house molasses.

Mr. James T. Gifford, who tried some experiments with the corn stalk, on examination, found that the butt of the stalk remaining in the field retained its juice and saccharine matter until the hard freezing in November caused fermentation to commence, from which time the saccharine matter was too acid. It is also said that sugar has been made of the water in which the ears of corn have been boiled; from whence it has been inferred that the cob contains much saccharine matter. Mr. Knapp, of Waynesville, Illinois, in a communication made to the Union Agriculturist, for October, published at Chicago, says: "I hasten to say, briefly, that I have made about six gallons of maize molasses from what was judged (not measured) a barrel of expressed juice of the stalks. I find there is no difficulty whatever in clarifying the juice with hydrate of lime, skimming until it boils, and then straining through flannel. An immense quantity of extractive matter in the form of a

fawn-colored precipitate is thus speedily got rid of, and the evaporation is then conducted in the same manner as in making maple sugar. There are two other mills in this neighborhood. At one of them, sixty gallons of molasses have been made from an acre. In regard to crystalization, I entertain no scruples, when the evaporation is conducted properly and carried to the proper points." The experiment has been also tried, it is said, in South Carolina, even to granulation, without difficulty, with perfect success; and confidence in its importance as a production is expressed.

In the number of the Albany Cultivator for January, 1843, a correspondent writes from Ohio, and, referring to an experiment of his own, says: "The result of this experiment has led me to the following conclusions:

"1st. That Mr. Webb's statement of the amount of sugar which can be made from an acre is not overrated.

"2d. That stripping the ears from the stalk is essential in the production of sugar, though not essential in the production of a much smaller quantity of excellent molasses.

"3d. That large stalks yield much more juice than small ones in proportion to their size, and that, consequently, the corn should be grown in drills, and not by sowing broadcast.

"4th. That the principal labor in making sugar from the cornstalk consists in stripping off the leaves, and that this is most expeditiously accomplished before the stalks are cut.

"5th. That three quarts of juice will yield saccharine matter equal to one pound of sugar; or that eight gallons of juice will make one gallon of thick molasses.

"6th. That the manufacture of sugar from cornstalks is an object well worthy the attention of every family who has even one acre of ground to cultivate."

Such are some of the results of very imperfect experiments, the first year after the announcement of the fact that sugar can be made from the cornstalk. They were commenced and prosecuted, in most cases, with the simple view of deciding a question on which, probably, nearly all who had just learned that such a thing was asserted, were, to say the least, somewhat skeptical. They, too, had no conveniences for the manufacture; and yet, with all these drawbacks to success, the question may be considered as fairly settled by a number of independent witnesses, who need only a knowledge of the process, and skill and experience in conducting the trial hereafter, to ensure complete success.—In order to aid in this desirable object, and as so many are interested in whatever may throw light on the subject, Mr. Webb's account, originally drawn up for the National Agricultural Society, will be subjoined in Appendix No. 3.

As numerous inquiries also have been made respecting the best process of clarification, a communication detailing the mode has been obtained from Professor Mapes, of New York, who has paid much attention to the subject, which will be found in Appendix No. 4. He, also, as will be perceived, expresses his conviction, from some experiments on the cornstalk, of its entire superiority over the sugar cane, if the enthusiasm of those who made the former experiments published did not lead them into errors.

The French scientific journals contain some notice of this subjebt, and a belief is there expressed that sugar can be manufactured from the corn stalk, and from the *fig cactus* found in the recent French possessions in Africa.

There are some facts stated in relation to the manufacture of sugar from the cane, which as they may apply also to that from the corn stalk, it is thought proper to subjoin. They have been mostly derived from Porter's Treaties on the culture of the cane. At 10° of Beaume's saccharometer, it is said, there are in 100 lbs. of cane juice or syrup 18 lbs. 6 oz. and 1 dr. of sugar. This, it will be perceived, is not more, if as much, as Mr. Knapp and others obtained from the corn stalk. The weight of water, besides what is termed the water of solution, to be evaporated to reduce the cane juice to a state of saturated solution, is 70 lbs. 9 oz. 6 dr. A saturated solution of cane juice contains five parts of sugar and three parts of water. This is indicated by 34° of Beaume at the temperature of 82 Fahrenheit. Seventeen ounces of lime are used for 300 gallons of juice. The greatest danger seems to be of using too large a proportion of alkali. The highest production of 100 gallons of cane juice for nine years average, on an acre of an estate selected in Jamaica, is stated to have been 122 lbs. of sugar. The experiments above cited, with respect to corn stalk, would show an equal, if not a greater average. It is evident that the whole difficulty of granulation may be obviated by boiling immediately and quickly in not too large quantities. The paper of Professor Mapes, in the Appendix, already referred to, will also furnish valuable information on this point. The Southern States, who have herctofore been engaged in the manufacture of cane sugar, possess peculiar advantages in this respect, as they are already provided with the requisite machinery for grinding and boiling, and can apply their already acquired skill no doubt with great effect. Hence, we need not be surprised, if we should hereafter find them taking the lead in this business. It is a truly gratifying reflection, that, while the temperance reformation is so greatly lessening the consumption of corn in the manufacture of whiskey, the introduction of this manufacture of corn stalk sugar promises to furnish a much more profitable as well as salutary application.

—

The following directions for its manufacture, furnished by Dr. Naudain, of Delaware, are the most clear and precise that we have seen:

"The fact that sugar can be made from the stalk of corn is one of recent discovery. It has already excited a deep interest in the public mind, and every thing relating to it is looked for with much interest.

"The writer has become possessed of some facts which may materially aid others in the present experimental state of the business. For as yet it is experiment, although enough is known to convince the most skeptical that the probability is that sugar from Indian corn will be, at a future and not very distant day, one of the great staples of the country.

"Without further remark, then, it should be remembered that as much corn-stalk as possible should be grown. To do this, the corn should be planted as broom-corn is commonly planted, very close in the row, probably a stalk every three or four inches. The tillage will be the same as for broom-corn. When the young ears begin to appear, it is necessary to pluck them off carefully, and to repeat the gathering as often as necessary, so as *to prevent the formation of any grain.* Because, if grain be allowed to form, it takes all the sugar from the stalk.—About the time the corn begins to harden, the making of sugar should be begun. It is not necessary to say any thing about a proper mill to crush the stalk and separate the juice, because mills of the cheapest kinds only should be employed now, until the business would fully warrant an expensive outlay. It would probably be found that the common cider mill, with plain cylindrical nuts, would be quite sufficient for a farmer who would raise a fourth or half an acre of corn for sugar for his family, and this quantity would be quite sufficient for satisfactory experiment.

"When the juice is separated from the stalk, about a table spoonful of white wash made of the *best quick lime*, and about the consistence of thick cream, should be added to each gallon of the juice, and then the boiling should commence. The scum that rises should be carefully removed; and the juice, if this process has been properly and carefully conducted, will be quite clear and nearly colorless. Then commences the process of evaporation; and when the juice has boiled down in about the proportion of eight gallons to one, the boiling will be completed, and it may be poured out into a shallow tight wooden box to grain.

"It has been ascertained, although as yet the reason is unknown, that if the juice be boiled in a deep vessel, like the common cooking vessels, sugar will seldom be obtained; while if it be done in a shallow vessel, so that the juice at the commencement of the boiling shall not be more than three to five inches deep, sugar would be obtained without difficulty. It has been ascertained also that the sugar from corn will not grain so readily as that from the sugar-cane.—And in some instances it has remained more than a week after the boiling before the sugar was formed, and yet excellent sugar made.

"It should be *particularly remembered* that the juice should be boiled *as soon as separated from the stalk.* It becomes acid very soon, and no sugar can be made if the juice be allowed to stand two or three hours before it is boiled. The juice will even spoil *in the stalk* before it is ground, if the stalk be cut off a few hours before grinding. It is necessary then that every part of the process should be done with the greatest despatch. The stalks should be brought to the mill as soon as cut, and ground immediately. The vessel for boiling ought to be properly filled in an hour, or at most two hour's grinding. And the process of boiling down should immediately commence and be continued until completed.

"Excellent syrup, superior to the best molasses, will be obtained by observing the above directions, and boiling five gallons of juice to one gallon.

"The juice of the corn-stalk is very rich in sugar when cultivated in the manner suggested. Tested by Beaume's sacharometer, the instrument used to measure the strength of syrups, the juice of the corn-stalk weighs 10 to 10½ degrees, which is about the weight of the juice of the best cane in the West Indies, and is richer than the juice of the cane in Louisiana, which is seldom heavier than 8½ degrees.

"One gallon of juice will produce nearly 1½ pounds of sugar; and an acre of good corn will yield, if carefully expressed, from 700 to 1000 gallons of juice."

CURE FOR A FOUNDERED HORSE.

I send you the following prescription, which you may give a place in your useful paper, if you think it will be of any advantage to planters and travellers.

As soon as you find your horse is foundered, bleed him in the neck in proportion to the greatness of the founder. In extreme cases, you may bleed him as long as he can stand up. Then draw his head up, as common in drenching, and with a spoon put far back on his tongue strong salt, until you get him to swallow one pint. Be careful not to let him drink too much. Then anoint around the edges of his hoofs with spirits of turpentine, and your horse will be well in one hour.

A founder pervades every part of the system of a horse. The phlegms arrest it from the blood; the salt arrests it from the stomach and bowels; and the spirits arrest it from the feet and limbs.

I once rode a hired horse 99 miles in two days, returning him at night the second day; and his owner would not have known that he had been foundered if I had not told him, and his founder was one of the deepest kinds.

I once, in a travel of 700 miles, foundered my horse three times, and I do not think that my journey was retarded more than one day by the misfortune, having in all the cases observed and practised the above prescription. I have known a foundered horse turned in at night on green feed; in the morning he would be well, having been purged by the green feed. All founders must be attended to immediately.

Southwestern Farmer.

Agriculture is the nursing mother of the arts.—*Xenophon.*

POUDRETTE.

We feel particularly anxious to call the attention of our farmers and gardeners to this convenient, stimulating and valuable manure. We had our own interest very much excited by the astonishing, and, we *guess*, rather exaggerated accounts we heard of its effects while we were at the North last fall. That it is one of the most powerful fertilizers known, and that it should be at least fairly tested by every farmer, who has an opportunity of obtaining a barrel, we do not hesitate to assert; and this, because the experiment can be made at so small an expense, and if it is all they say of it, it will prove the most important addition that has ever been made to the farmer's resources. That it is ever to supersede stable manure, or that the day will ever come when it will be to the farmer's interest to neglect his farm-yard and compost heap, we consider all humbug and nonsense. But that after the farmer has put out all the dirt, dung and compost that he can rake and scrape, that he may then purchase poudrette for the balance of his land, that would otherwise go unmanured, with a prospect of realizing two or three hundred per cent on the outlay, we are strongly inclined to believe.

All chemists agree in according to this substance the very highest fertilizing properties.—Prof. Johnson, than whom none stands higher in the scientific world, says:

"'*Night soil*' is probably the most valuable, and yet in Europe at least, the most disliked and neglected, of all the solid animal manures. It varies, no doubt, in richness with the food of the inhabitants of each district—chiefly with the quantity of animal food they consume—but when *dry*, no other solid manure, weight for weight, can probably be compared with it in general efficacy. It contains much soluble and saline matter, and as it is made up from the constituents of the food we eat, of course it contains most of those elementary substances, which are necessary to the growth of the plants on which we principally live."

We have heard it estimated that one bushel of poudrette contained at least as much fertilizing power as ten bushels of stable manure, while the facility of putting it out was much more than ten times as great. It has been applied in this country with great success to wheat and corn. Upon potatoes, peas, turnips and other garden vegetables, it is described as producing the most astonishing effect in hastening their maturity and increasing their products. In a letter to the "United States Farmer" Mr. Jos. Tyrell, of New Jersey, states:

"In March last I planted six rows of early peas, four of the rows were manured with poudrette sprinkled liberally over the seed. These came up five or six days before the others, they grew more luxuriant, came in blossom ten days sooner, and yielded much more abundantly than those which had no poudrette. I have tested its merits as a manure for cucumbers and melons, and prefer it to any other for those articles."

Mr. Lemuel Soper, of Long Island, makes the following statement:

"I have used poudrette on corn at the rate of a gill to the hill, which produced as good corn as where I put a shovel full of yard manure in the hill. The worms were not as troublesome where poudrette was used as where other manure was used. I also used it on wheat, at the rate of forty, sixty and seventy bushels to the acre. When I used forty bushels to the acre, I got *as good wheat* as where I used forty wagon-loads of barn-yard manure, and *equally as good* as where I used sixty or seventy bushels of poudrette to the acre.

"I also used it on all kinds of garden vegetables, and never had better success. I consider it *better for corn in the hill than bone*."

Mr. F. W. Blydenburgh says:

"On *grass lands*, in the month of May, it has a *decidedly* beneficial effect as a *top dressing*. I should think twenty bushels to the acre would *double* the crop for one year, but doubt whether it would show much on the second. Mr. Blydenburgh has used it on nearly all the variety of crops raised on Long Island, and with a view of testing its relative value with other manures. He says, 'I applied the article last summer to Indian corn, melons and other vines, and ruta baga. On corn, a gill was put in the hill, against *eight times* the quantity of hog-pen manure, and against *five* times the quantity of fish manure, the latter a compost of 'sting Rales' and earth, prepared the previous autumn, with results much in favor of poudrette for the first six weeks, after which its superiority became less manifest, until the general appearance and crop became so nearly equal that no difference could be perceived. * * * In conclusion, I would say that for the hills of corn, poudrette has no rival, so far as the labor and expense on the one hand, and produce on the other, are to enter into the account. A gill to the hill is better than a larger quantity, unless the first four weeks after planting should prove to be very wet, or unless the ground is low and moist. I have seen a striking instance of the good effects of poudrette on a field of oats, applied by one of my neighbors at the rate of fifteen or twenty bushels to the acre, on land of middling quality. The yield was increased at least 70 per cent."

For the information of those who have already ordered the article, as well as those who may conclude to do so, we copy the following directions for its use, furnished by Mr. D. K. Minor, of New York:

"I recommend the use of 20 to 25 bushels to the acre for corn, on ordinary land. When the ground has been ploughed, and lays in furrows, I would spread by hand, at broadcast, about 14 or 15 bushels to the acre, and then harrow *crosswise* of the furrows, mixing it *thoroughly* with the soil. I would then mark out the rows with an ox chain, drawn on the ground, and drop the corn, and put about *half a gill in the hill*, and cover it up *with* the corn. This would require near 8 bushels, making about 23 bushels per acre,—*or* three-fourths of a gill may be put *in the hill* at planting, and an equal quantity spread on at broadcast, and well worked in at the first or second hoeing—*or*, if not obtained in time for planting, the *whole* may be spread on, and thoroughly worked into the soil at the hoeing. It is undoubtedly most effectual when applied at planting; but still, very important benefit will be obtained from its application when applied at the rate of 14 or 20 bushels to the acre at the first or even *second* hoeing.

"*For wheat*, to be followed by *grass*, I would spread on at the *sowing* from 15 to 20 bushels to the acre, to be harrowed in *with* the seed. This will give it a vigorous growth in the fall, and enable it to stand the winter. I would also spread ten bushels more upon it in the spring, and pass a light harrow and roller over it. When used as a *top dressing* for wheat or grass, without being harrowed in, it should *always* be just previous to a shower.

"It is found to act very favorably on grass seed, *especially on clover*. I have reports from Dutchess and Westchester counties, which say that where poudrette was used on wheat in 1839 and 1840, the grass, *especially the clover*, is much better than where other manure was used in the *same field*, so much so indeed, that it is readily perceived on going into the field.

"For *turnips*, 25 or 30 bushels is a good dressing. If the seed is sowed at broadcast, the poudrette should be applied in the same way and harrowed in with the seed. For *buckwheat*, 10 to 12 bushels; and for *oats*, 15 to 20 bushels, according to the condition of the land, may be used, *always* to be harrowed in with the seed. For *potatoes*, a *gill* to the hill, to be put in with the seed, is sufficient on ordinary land; a larger quantity will be likely to make more *vines* than are useful.

"For *cucumbers*, *melons*, and other garden vegetables, it may be used in small quantities at *planting*, and on melons, cucumbers and squashes, it will be found a *preventive* to the *striped bug* and other insects, if sprinkled over them in small quantity after they are fairly up. ☞I find the same *prejudice* and *dislike*, on *first* acquaintance with it, among *insects* as among *some men*. On applying it to cucumbers and melons, I was amused to see the *yellow bugs*, and other like *fastidious* insects turn their backs upon me, as I have often been to see gentlemen of *delicate* nerves turn up their noses at the *mention* of 'poudrette!' This circumstance, however, may not render this valuable fertilizer of *less* value, any more than the opinion of *gentlemen* of 'delicate nerves' renders the enterprise one of doubtful propriety. I am satisfied from my own experience, that it will be found very valuable on all garden vegetables, not only in producing a rapid growth, but also as a guard against *insects*."

Southern Planter.

POUDRETTE.

In running over the articles in the last number of your valuable paper, I was particularly struck with the one from your correspondent Za. Drummond, Esq.—it made every cord in my heart vibrate, and I felt, for one, than I was ready "to go hand in hand" with him, if not for "twenty-five years," at least to the close of my earthly existence, in attempting to improve that part of the Old Dominion which I call my own. I believe it was General Miller who, during our revolutionary struggle, when asked by his superior officer if he could storm a certain fortification of the British with an inferior force, modestly answered, "I will try, sir"—he made the effort, and history has recorded the result. I have adopted this as my motto—I am determined to "try" what can be done. I remember to have promised you some time ago a short account of my method of preparing manures from human excrements. I will now redeem that promise, hoping that it may be useful to many of your subscribers. First, I collect the stercoraceous matters separately in large vessels or hogsheads, after the urine has become putrid, which will require but two or three days in warm, and ten or fifteen in cold, weather. I then add sulphuric acid to the urine slowly; if the urine is putrid, a powerful effervescence will immediately take place; the acid must be added until effervescence ceases. By this process, the carbonic acid in combination with the ammonia, is disengaged and driven off, and sulphate of ammonia is formed, which has no volability, except at a very high temperature. Thus you secure the ammonia formed by putrefaction, which otherwise would escape. I then add the liquid to the solid excrements, incorporating them well together, until a very thin batter is formed; into this mass I stir in finely pulverized charcoal, according to my judgment, without regard to any precise quantity; this done, I spread the mass upon boards made tight, in the open air—stir frequently until the whole is dry, then pulverize with a spade, and barrel it up for the use of crops.

My drying boards are protected from the weather by a shed open to the south, so as to receive the benefit of the sun. Manure made in this way I call *Poudrette*, and of its value I can speak in the highest terms. When properly made, it is inodorous, and the application to crops easy, and the effect powerful. I made an experiment with it last season upon sugar beet, in comparison with bone dust, bone dust and stable manure mixed, and stable dung alone. The beets manured with poudrette came up quicker, grew faster, and maintained a decided superiority to the last, making the largest and best beets; the quantity of poudrette was only a small train to each drill. I used it also upon corn with entire success. In this experiment I subjected it to a very severe test; I selected a very poor spot, put only one and a half gills to the hill as a top dressing at the time of planting, and the result was truly astonishing, proving it to be beyond all doubt a manure of great strength and power, perhaps surpassing all others *now known*.

It must in all cases be used as a top dressing; such is its strength when planted with seed, the

germ is destroyed, and consequently does not come up.

I shall make about one hundred barrels this season, which I intend to use chiefly on corn the coming spring, from which I anticipate the best results.

When I commenced I intended to say something about what I have been doing in bone dust, dead horses, pigs, dogs, cats, &c., but I am reminded in your editorial what great severity your correspondents may expect at your hands, and as my piece is already much longer than *my "hand,"* I shall close. Sincerely yours,

GEORGE WOODFIN.

Southern Planter.

ROOTS.

From the very flattering manner in which you have introduced me to the readers of the "Southern Planter," I cannot resist the call to furnish you with a statement of the treatment, culture and produce of my carrot patch and field of Swedes.

I am not so vain as to think I can furnish any thing new on the subject, to your readers; but a plain, practical, matter-of-fact account may not be uninteresting to them.

Although the root culture has been gaining favor in this country for several years, still, in my opinion, it has not received that attention it deserves. My soil is a loam, some parts inclining to sand and some to clay, and what is termed here sandy loam and clay loam, and well adapted to the growth of roots, particularly carrots and ruta bagas. I have cultivated roots for my stock for the last ten years, and I have found no crop that pays better for the expense of cultivation; none that abstracts less from the soil, or that leaves it in a better condition for a succeeding crop. I have never failed in procuring a good crop of barley, and after ruta bagas, grass seed always take well. I have been less successful with oats, as the richness of the soil causes a too luxuriant growth of straw, whereby they lodge and do not fill so well.

You may recollect that my carrot patch was near my house; I call it my *accommodation* crop, from its being near by and can be worked at odd times; besides it is the scene of my labor! Do not start, gentlemen, for I assure you I do not belong to the silk-stocking gentry. If you had made your visit in the summer, you might possibly have found me in my "frock-and-trousers" in the very midst of them, and the perspiration profusely rolling off my face in drops as large as peas.

To ensure a good crop of carrots, and it will apply equally well to all crops, it is necessary to have the soil not only rich but well worked and pulverized. As soon as the soil is sufficiently dry in the spring, I plough as deep as possible, and after one or two weeks, I haul on at the rate of sixty cart loads, (equal to thirty wagon loads,) of compost manure, and spread evenly, and harrow it thoroughly, when the plough is again put on and a shallow furrow turned, just sufficient to cover and mix the manure with the soil. It is now suffered to rest until the seed is to be sown, which in this climate will be from the 10th to the 20th of May. Previous to sowing it is thoroughly harrowed, and then thrown into ridges, twenty seven inches apart, which is done by turning two furrows together. A light roller is then passed over, flattening two ridges at every turn, the horse walking between them. This leaves a flat surface of about four inches wide for the drill, which follows and deposites the seed in the centre about half an inch deep; a small roller attached to the drill follows, covering and compressing the earth to the seed, which completes the operation.

As soon as the plants are about an inch high, they are weeded and thinned, which is considered the most tedious operation, which is rendered easy and expeditious by what we term the "push and pull" system. In the first place we run the cultivator, with the wings closed, between the rows, and then by standing in the furrow, with a small narrow hoe, say three inches wide, push one side of the plant and pull the other side into the furrows, which will leave the plants about four or five inches apart, which I conceive to be the proper distance. After the second working, which is merely running the cultivator between them again and cutting up the weeds, the ridges vanish and the soil becomes nearly level.

The advantages of cultivating on ridges are, the soil is warmer and drier, the plants are more easily distinguished, the weeds do not grow as vigorously and are much more speedily removed. The great secret in making good root crops is in thorough cultivation and a generous supply of manure.

You will recollect the carrot I cultivate is the white Belgian variety, which I esteem the most profitable on account of the great produce and the ease with which they are harvested.—Unlike any other variety, from three to four inches of the roots rises above the soil, which affords greater facilities in drawing, which can be done by grasping them with the hand, resembling in that respect the mangel wurtzel.

I gathered them on the 14th of October, which was accomplished in the following manner.—Each man took two rows, pulling and laying the tops all one way in a row. After they were all pulled, the tops were struck off at one blow with a knife made of a piece of an old scythe, and the roots of four rows were thrown into one; the cart followed and the roots were tossed into it with the hand. The crop obtained from the patch, which is about one-third of an acre, was 305 bushels.

It is impossible for me to estimate the expense of this crop, as the labor was done at odd times, in the morning before breakfast, when the main work was at a distance. In comparison with the ruta baga, I judge they cost about one-third more, which would bring them at about nine cents per bushel.

I agree with Mr. Botts in estimating their value. For horses and milch cows, I consider them superior to any other root. Horses become very fond of them, and fed once per day with them, their bowels are kept loose, and the hair becomes glossy, giving them a lively and healthy appearance. Cows eat them greedily and their milk is of the richest color, and the butter of superior quality. They are in such high estimation in this section, that a gentleman in the city paid me twenty-five cents per bushel for a load of them to feed his cow.

From the amount taken from the small piece as above, I am well persuaded that 1000 bushels, every thing favorable, can be grown on an acre.

My method of cultivating the ruta baga is similar in several respects to that of the carrot. They require a lighter soil and delight in a sandy loam, and will bear as much manure as any other crop, not even excepting corn. I have grown good crops on a sod, by turning under forty loads of fresh yard manure. I prefer, however, to have them succeed potatoes, which was the case with the field you saw in October last.

Last spring a compost of yard manure and the refuse of a glue factory, consisting of lime, bones, wool, hair and bits of pelt, was applied, say twenty loads to the acre, carefully spread after the first ploughing, and turned under with a shallow furrow and thoroughly harrowed and mixed with the soil—then throw into ridges 27 inches apart, the tops flattened with the roller, and the seed deposited with the drill, &c. The after culture, with the exception of leaving the plants from nine to ten inches apart in the drills, was the same as that of the carrots.

There is one fact in regard to this crop which I never noticed until last summer. It so happened that a part of this field was not weeded and thinned for some days after the other, and the plants and weeds had attained considerable height before they were worked, and caused about double the labor to finish them. On pulling we found them on this part of the field less in size, necks long and tops large—termed "necky." On reflection, the same has happened before, and I could not account for it. I have also heard others complain of the quality of their seed, that the plants would not bottom, &c. I have seen some of these patches and recollect that they were very close, and there was apparently a great strife between the plants and weeds for the ascendency.

I finished pulling my crop on the first of this month, and they amounted to 2355 bushels, and as near as I can make it out, the expense of cultivation would not vary much from six cents per bushel. We think there was not far from three and a half acres. I feed them to my cattle, sheep and swine; and for feeding calves the first winter, they are invaluable, carrying them thro' in fine condition, and promoting their growth wonderfully.

In storing them I fear the heat more than the frost. I have about 1600 bushels in a cool cellar and 600 in heaps covered with straw and earth, for feeding my ewes in May.

C. N. BEMENT.

Three Hills Farm, December 6, 1842.

Southern Planter.

RUTA BAGA.

In my communication on the culture of the white carrot, I promised to give you my method of cultivating and the product of my field of ruta bagas.

The piece you saw, when at my farm, contained about three and a half acres, and had lain in pasture a number of years; it was carefully turned over in the fall of 1840; and in the spring following, cross-ploughed and harrowed, and laid out in furrows two and a half feet apart, and planted with potatoes. The knolls, which incline more to sand, were manured with horn-shavings and hogs' bristles, one handful to each set. Twelve rows through the middle were manured with salt mackerel, which were spoiled, half a fish to every set. It was an unfavorable season for potatoes, a severe drought in the summer having injured their growth. The rows manured with the salt fish, I noticed, stood the drought much better than any other part of the field; vines large and of a dark healthy color, when the others were brown and shrivelled, and on digging we found them of a large and even size, and of excellect quality, and the yield far better than any other part of the field.

Last winter, I purchased twenty-six two-horse loads of the refuse of a glue factory, consisting of lime, bones, wool, hair and piecess of pelt, some of which had lain for two or three years. To twenty loads of this I added forty loads of yard manure, and had it well mixed. In the spring it was ploughed seven inches deep, and left until the middle of June, when the manure was hauled on and evenly spread, which covered all except about three-quarters of an acre, on which was put six loads of the factory refuse, without any yard manure. The piece was then ploughed and harrowed, thoroughly mixing the soil and manure. It was then thrown into ridges twenty-seven inches apart, the same as for the carrots; tops flattened with the roller, and seed deposited with the drill (Bennett's) on the 18th of June.

On that part of the field where the yard manure was applied, the plants made their appearance on the fourth day after sowing, while on that part where the refuse of the glue factory was put, they showed very few plants until the tenth day, and then they were sickly in appearance, and grew so tardily, that the flea devoured them about as fast as they made their appearance. In fact, we were obliged to transplant to fill up vacancies, on the whole three-quarters of an acre—showing most conclusively the ruta bagas require a quick and active manure to give them an early start to get them out of the way of their greatest enemy, the turnip flea or beetle.

On the 18th of July, the cultivator was run between the rows, and they were thinned with the hoe in the same manner as the carrots, leaving the plants from eight to ten inches apart in the drills. In August, the cultivator was again run through them, and they were howed at in-

teryals when convenient. Nothing more was done to them until we commenced pulling in November. The crop measured 2355 bushels. I will here remark, that when the salt fish was used the year previous, it was strikingly visible at some distance; the tops being of a darker hue, higher and more vigorous, and they continued so through the summer, and on raising we found them thicker and longer in the neck and smaller in the bulb, showing that salt will increase the top at the expense of the bottom.

The greater part of the crop was stowed in a cellar—the remainder was put in heaps in the field, for feeding my ews when they have lambs in the spring. The heaps are made in the following manner, which I never knew to fail when they were properly attended to. A trench six feet wide, of any length required, and one foot deep, is dug in a dry situation, generally on a knoll; the roots are thrown into this trench and piled up in the form of a roof. A coat of straight straw of from eight to ten inches in thickness, is put on in such a position as to conduct the water off, if any should reach it. Earth is now thrown on by digging a trench around the heap, beginning at the bottom and going around until the whole is covered. The earth will press the straw, which prevents its running through to the roots. A coat of ten to twelve inches in this climate is sufficient for our common winters. The trench will prevent the water from getting into the heap. There is more danger of getting the covering too thick than too thin. I have suffered more from heat than frost. After the earth is all put on, it should be carefully clapped down with the spade, to make it more effectually shed the rains. After a few days I take a crowbar and thrust it in the top along the ridge down into the heap, no matter if it breaks some of the roots, and open holes about three feet apart, to let the gas or vapor off, which is generated by a partial fermentation. A flat stone, raised a little on one edge, set up an inch or two, or a wisp of straw may be put into the holes to prevent the rain from getting in, which completes the work for the winter.

With me the ruta baga is a valuable crop.—They afford the greatest quantity of food for my stock, from an acre, while they seem to exhaust the land less and leave it in the best possible condition for a succeeding crop. It is too rich for oats, but well calculated for barley, and clover seed always "takes well," sown with it. I feed them to my cattle, sheep, hogs (boiled,) and occasionally to my horses. For calves, the first winter, they are very valuable, keeping their bowels open and loose; they will grow and thrive without running too much to fat; their coats smooth and glossy, and continue to grow through the winter, and "go to grass" in fine condition, by which they gain at least six months in their growth over those wintered in the common and ordinary way. Heifers wintered in the above manner will answer to come in at two years old. I have one now in my yard that will not be two years old until January next; she had a calf last March, and has been milked ever since, and I cannot perceive that her growth has been retarded in consequence, and she is now as large as common three year olds.

C. N. Bement.
Southern Planter.

Soap Suds.—There is no better manure than dirty soap suds; and there is not a farm house in the country, but what produces enough of it in the course of a year, to manure a garden, two or three times over. Dirty suds, after washing, is almost universally thrown into the nearest gutter to be washed away and wasted. Would it not be an improvement, and show a laudable economy in the good woman of the farm house, to have it conveyed to the garden to enrich the ground, and make the vegetables grow more luxuriantly? The potash, the grease and the dirt, all of which are component parts of soap suds, are first rate manures, and should always be applied to make plants grow, and especially when hard times are loudly complained of and sound economy is the order of the day.

IMPROVEMENT OF INDIAN CORN.

I have several times, within the last fourteen years, called the attention of the agricultural public to the subject of improving Indian corn, without, so far as I am informed, having induced a single experiment to be made. This shall not deter me from making another effort, however. At the present time there is not a single variety of corn that has not some objectionable quality, and not one bad quality that may not easily be got rid of. One variety is excellent in every quality except its lateness in ripening; another is early enough, but its grain is too small and its cob too large for profit; another is too flinty, another too chaffy, &c. Every corn planter will agree with me that it is important to have a variety of corn that will ripen early, that the ground may be occupied by a crop of wheat or other winter crop, and that the corn may be housed, (and marketed, if desirable,) early in the season. But I need not dwell on the qualities that are desirable, as they will readily suggest themselves. I therefore proceed to state, that any farmer may make any or all of the following changes in his corn. If it be too late in ripening, but possesses every other desirable quality, he can readily make it *early;* if it be sufficiently early, but objectionable in other qualities, he can readily improve those qualities. And all this too by a means just as simple as that of any other agricultural process.

Corn has the male and female organs in different flowers on the same plant. It is called by botanists a *monœcious* plant on this account.—The male flower is on the top of the plant, and is commonly called the *tassel;* the female flower is on the ear, and is called the silk. If the plant be deprived of either of these organs, no grain can be formed. Suppose we deprive a plant of all the silk as soon as it appears; we shall find the cob will grow and present all the indications of germs of grain, but there will be no grain; and exactly the same thing will happen if we destroy the tassel as soon as it appears, without touching the silk. Each thread of the silk leads to a particular grain on the cob, so that there are just as many threads of silk as there will be grains of corn on the cob when ripe. The cob and the germs of grain will be formed whether the male influence be exerted or not. The male influence, therefore, will not change the size of the cob, the size or shape of the grain, or the number of grains on the ear; but it does affect the color of the grain, and its quality as to flintiness, and as to its season of ripening.

Now let us suppose an experiment to illustrate the facts just stated. I have a kind of corn that suits me exactly in every quality except its season of ripening, and I wish to obviate that difficulty. Well, I plant a piece of ground, say a quarter or half an acre, with it at the usual time, taking care to leave each alternate hill vacant. Say this corn ripens on the 1st of October. I want it to ripen on the 15th of August. I then look for some early variety that ripens on the 15th of August, say the *Tuscarora,* whose grain is light and chaffy, but which is not otherwise objectionable. I plant this in the alternate vacant hills six weeks or two months after I planted the first parcel. It will of course happen that both kinds will put forth tassels and silk about the same time. Now I wish to transfer the grain of my first planting to the cob of the second; therefore I carefully watch the appearance of tassels on the Tuscarora, and cut them out as soon as they appear, not allowing them to produce their pollen, and thus allowing the silk of the Tuscarora to be affected by the pollen from the neighboring late kind. At the harvest I save only the ears of the Tuscarora, and, as there are plenty of them, I save only the earliest and best formed. The grain on them will be found to be a perfect mixture of the two kinds. Next spring I plant the product, and at harvest I find about an equal quantity of grains on each ear of each of the parent kinds, in appearance. I select these I prefer, and plant them on the third year, when I shall have secured the improvement I desired.

In this way the grain may be transferred from a red cob to a white cob, from a large cob to a small cob, &c. The grain of the large southern corn may thus be placed upon the cob of the dwarf northern corn, and indeed any other improvement or change desirable may be effected. True, it requires three years to effect the object; but what of that? Nothing is lost by the experiment except an hour or two of time, and a little careful watching. Not a fourth as much time or attention is required as is bestowed on the production of improved animals.

I could enlarge upon the importance of this subject, and fill a large space in your excellent Register with the discussion, but it surely cannot be necessary. There is not a corn planter in the union that has not every year had cause to lament some bad quality in his corn; and I take upon myself to say there is not a single bad quality that may not easily be removed by the above described process. I hope, therefore, that some one will make the experiment and publish the result for the benefit of the agricultural community.

Gideon B. Smith.
Farmers' Register.

CORN.

"I have noticed an error in the culture of plants and trees, wherever I have been, and I know no better plan to illustrate it than in showing the effect of the error on corn. In the culture of corn, it is usual to work the crop till the tassel is about to make its appearance; this is an error. Whenever the lateral roots of a plant are injured, moved or disturbed, when the stalk that is to produce the seed is matured or about maturing, or whenever those roots are covered to a greater depth at this stage of growth than nature intended, it will produce early maturity and decay; and the yield will be just in proportion to the extent of the error. If you will take the pains to destroy the lateral roots of a stalk of corn after its having made the last joint on the stock, you will find that it will produce no corn; and if you will displace their situation at this time by hilling, you will get a less quantity of seed than if left alone. If the lateral roots of a stalk of clover are cut off when the seed stock is forming, there will be no seed; and just so with other plants and trees; and the working of them at this stage cannot be attempted without injury. Yet, strange to say, it is almost invariably done. I have never suffered my corn to be worked after one-third of the height of the stalk was attained. I plant close enough to have the corn to shade the ground at this height, so as to prevent the growth of weeds after this last working. I plant two and a half feet square, and leave two stalks in the hill, and I have never missed having as much corn per acre and as large ears as my neighbors; and much more than some of them. I never planted a crop of corn that I had not some kind neighbor or friend to tell me that I would have neither corn nor fodder. Last spring a cropper upon my neighbor's farm planted thirty-five or forty acres in corn, and I about ten acres; our fields adjoining. He planted his corn four feet square, and left three or four stalks in the hill, and worked his crop till it was ready to shoot into tassels. I quit working mine when about two and a half feet high. His field was full of weeds and grass. Mine remained clear of both weeds and grass. When our corn was husked and housed, he told me that I had from my ten acres nearly fifty bushels of corn more than he had from his thirty-five or forty acres, notwithstanding he told me, in its early growth, that I would have no corn. Part of his ground was quite as good as mine.

"A similar and worse effect is produced in the hilling or working of plants in the latter stage of their growth, than takes place in plants and trees when deep planted. A disease is produced that hurries the plant on to early maturity by impeding the proper nourishment, by disturbing or placing the roots below where nature intended they should range for food, as well as depriving the vessels of the stalks thus covered from performing their functions. The stalks

being established, it is folly for man to attempt to do that which God alone can do. Deep planting and ploughing the peach orchard after the trees have maintained sufficient maturity to produce fruit, is, if not wholly, the principal cause of the disease called the yellows. By ploughing, the lateral roots are either cut, disturbed, or forced to seek food apart from where nature intended, and thus operates as a hill placed around plants, and brings the tree to early decay.

"To conclude this subject for the present, I will say, work your plants and trees while young, so as to form good stalks, and then trust to that all-wise Disposer of events to perfect them.

"I think I noticed a remark in your paper, of the roots of the watermelon being attacked by small animalculæ. Some salt added to the hills before planting will remedy that evil and give you better fruit; and salt and satpetre sown in the peach orchard, (particularly where the orchard is worked with the plough,) will assist in preventing like depredations to the roots of the peach tree.

"If you think that this hasty notice will be of any service, you are at liberty to dispose of it as you think best, and be assured that I seek neither money nor thanks for performing duties we owe to one another. LITTLETON PHYSICK."

Cultivator.

INDIAN CORN AND OLD FIELD PINES.

I have been a subscriber to your paper ever since it has been published, and I have noticed that nearly all your correspondents upon the subject of Indian corn agree that the rows should be four and a half or five feet distant. This is no doubt the proper distance for all the corn east of the Blue Ridge, but I once happened to be present, in the southwestern part of Virginia, at corn planting time, and was surprised to observe the farmers laying off their rows from three feet to three and a half wide. I told them that they would make no corn, and insisted that the rows should be wider. One gentleman told me to lay off a few rows in the old Virginia style, and I, being accustomed to the plough handles, laid hold and run off a few furrows through the centre of the field, four and a half feet apart. In the succeeding August, I visited the same field, and, to my utter astonishment, the rows I had lain off were destitute of grain, and the fodder burnt entirely up, whilst the narrow rows were excellent and the fodder green to the ground. So I concluded that the proper width of rows depends upon the nature of the soil. I noticed that the lands in Western Virginia dried much sooner after heavy rains than they did east of the Blue Ridge; this is the case in all limestone countries, where the corn must be planted thicker, for the purpose of shading the ground, and retaining the moisture in summer.

I congratulate neighbor Drummond on his converson to early planting. I have tried the experiment myself, and find that corn planted early will not grow as tall, but will yield more grain, and that of better quality, for it will weigh more to the bushel than the late planting.

A writer on "Forest Trees," in your August number, 1842, observes that old field pine is "of little value." Now I consider a grove of such pines exceedingly valuable for garden posts, or posts of any kind; if properly prepared, they will last as long as locust or any other timber.—My mode of treatment is as follows: I take a drawing knife and draw off the bark as the tree stands, as high up as I want to use it: in this situation the tree, which will not die, remains a twelvemonth, when, in consequence of the sun having drawn the rosin to the surface, it will have become a solid bulk of lightwood and will be ready for use.

Your obedient servant,

J. H. FUQUA.

Southern Planter.

Rubbing the limbs of the plumb with soft soap, to prevent the black canker, has been tried with success.

ON THE VALUE OF LIME.

It is discouraging to preach to a deaf congregation; or, what is practically the same thing, to address those who are resolved not to abandon long established practice and usage. Yet social duty may require us to give our fellow man the benefit of our experience and practice, and leave him to pursue his own may, be that what it may. After more than forty years of practice and industry devoted to agriculture, and almost sinking under hopes deferred, I commenced the free use of lime. In wet land, except for grass, lime was almost a failure; but upon dry land it appeared to wake up the sleeping powers of the earth, and run vegetation into a kind of unregulated madness. Mother Earth appeared to strut in pride for the richness and abundance of her productions. That great man, Moses of the Jews, you will remember, was forty years in the wastes and deserts of the earth, and, except the performance of his duty, his only gratification was a few bunches of grapes. Mine would seem to be a fate more gratifying to human nature, for I am left to wade through grass and corn, and flatter myself that I am at least upon good terms with dear old Mother Earth, who sooner or later must take me to her lap, and hush me to such repose as my deeds in the flesh may deserve.

If I were to fill one hundred pages upon this subject, the whole would resolve itself into this:—make your land dry, plough it well, give it 100 to 200 bushels of lime, or more if necessary; then all the vegetable matter or rich earth you can find—take a crop and lay it down to grass—not less than two gallons of clover seed to the acre, and as much of timothy as you please.—Vegetables, like carnivorous animals, eat or live upon each other—the more you give the earth the greater will be the following crop. No animal can be grown without food, and the same is the law of grains and vegetables. Our hot midday sun is taken up by the corn plant upon good limed land until it is of a deep black green; there is no wilting or twisting in its blades; the long silks show that all is well, and that there is no shuffling in the ranks. But to bring this matter into dollars and cents: I have no hesitation in saying that if I had been in the use of lime for forty years, it would have been good for one hundred thousand dollars upon my 500 acres of fallowed land.

LIME.

Farmers' Register.

HOW TO MAKE GOOD COFFEE.

The question is often asked, why it is, that good coffee cannot be produced in this country? The reason is simply this: coffee is spoiled in the burning, and sufficient care is not taken in preparing it for the table. To make coffee equal to the French is very simple, and very easy, and for the benefit of all good housewives, and all lovers of good coffee, we will state the manner in which it should be done. First, procure the best coffee possible. See that your cook does not *burn* it, but roast it to the color of a golden brown, and never allow it to remain in its burnt or roasted state for more than three days, as after that time it will lose its strength. Secondly, in *lieu* of the ancient method of *boiling* your coffee for an hour or more over a hot fire, and then being obliged to settle it with such rarities as *fish-skins, egg-shells* and the like, procure a *biggen*, as it is termed and make a distillation or decoction by putting the coffee in the apartment in which the strainer is, and turning thereon *boiling hot water*. Take care that the nose of the coffee-pot has a stopper to prevent the steam from escaping, and cover the top of your *biggen* immediately after having turned the water upon the coffee; as it is a most important requisite to have the steam confined. Judgement is also to be used, as to the amount of coffee required, and also to the quantity of water to be used. The best coffee may be spoiled by too much water applied to it. The coffee should be made very strong; and, if strong enough, its color will be quite black. Lastly, having made your coffee of great strength, do not use *hot water* to dilute it, but, in lieu thereof, take boiling hot milk, and weaken the coffee to your taste. By following these directions you will have as fine a cup of coffee as can be made in any country.

The time required for making coffee in this manner, is but a few minutes, the coffee being made as fast as the liquid issues through the strainer.—*Daily Times.*

SALT.—I will give your readers some account of the benefit of salt, as it is becoming an important article among farmers. I observed two years ago in the town of Stow, an acre of land set with fruit trees of different kinds, and I took notice that one half of the trees were one third larger than the others; and I also observed that where the trees were largest the land was moist, while the other part was dry. That half of the acre that was moist, and on which the trees were largest, was sown over with two and a half bushels of salt four years before; the other part was dressed with two cords of manure. The part manured with salt appeared as though there had just been a shower upon it; while the other part was dry and dusty. On the part to which salt was applied, the trees were smoth and thrifty; on the other part, the trees were rough and backward. Salt is good to destroy insects that are injurious to fruit. By mixing it with peat mud and laying it around fruit trees, early in the spring, it will destroy the insects that often injure the plum, the apple and peach tree.

GEORGE W. MAYNARD.

Boston Cultivator.

NUTRITIVE QUALITIES OF CHARCOAL.

Though the importance of mixing charcoal with the food of animals, particularly that of swine, has been generally acknowledged, and its benefits extensively tested, still it has been supposed that it only acted as a corrective to the acid tendency of food, and facilitated fattening by improving the health of the animal. Some experiments are, however, on record, which would seem to show that charcoal acts a more important part in the matter than has been usually assigned to it.

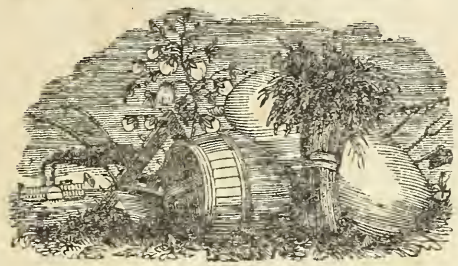
In 1793, a family being driven from New York by the fever, were absent six or eight weeks before it was deemed prudent to return. A number of fowls confined in a loft to the workshop of the house, were forgotten at the time of leaving, and it was known that there was nothing provided for their subsistence, it was expected on the return that they would be found starved to death. To the astonishment of all, the fowls were found alive and fat, though there was nothing upon which they could have fed, except a quantity of charcoal and shavings, water being supplied from the grindstone trough.

These facts coming to the knowledge of a gentleman in New York, as we learn from the Recorder, he instituted the following experiment. He placed a turkey in a box or enclosure, four feet long, two feet wide, and three feet high, excluded light as much as could be done, and allowed a free circulation of air, and fed the turkey with soft, brick, broken fine, pounded charcoal, and six grains of corn per day. The box was kept locked. At the end of a month, the turkey was killed in the presence of several gentlemen, was large and heavy, and on being opened was found filled with fat. Nothing, on dissection, was found in the gizzard and entrails but charcoal and brick. Last winter the experiment was repeated, and with the same success.

Several years since, in fitting out one of the Liverpool traders at New York, a pig on board was missing, and was supposed to have been lost. The cargo was taken on board, stowed, and the vessel sailed. It was now discovered that the pig was alive in the coal hole, but as he could not be got at readily, it was concluded to leave him to his fate. He remained in this retreat until the passage was made, when his pigship was found to be not only alive and well, but materially improved in condition, though there was nothing, coal excepted, he could have swallowed.

When it is remembered that wood, sugar and

several other substances, some of which are most nutritive, are compounded of nearly the same original elements, it would seem possible, by animal chemistry, to convert them to saving life; though all experiments with wood or charcoal failed. The German chemists have converted wood into very palatable bread, by roasting and pulverizing; but calcination, it has been supposed, would destroy whatever powers of nutrition wood might originally contain. The chemical action of vegetables seems to produce the least effect on coal, and not the least particle of it has ever been found in the structure of vegetables, though mixed with the earth and water in which plants were growing, in the form of the most impalpable powder. Whether animal chemistry is able to do what vegetable organization cannot, remains to be seen; though if there is no mistake in the statements alluded to, it would seem probable that this intractable substance is, in some way, made subservient to the nutrition of animals.—*Genesee Farmer.*



WEDNESDAY, MARCH 29, 1843.

POUDRETTE.

The attention which this manure is exciting in every section of the country where it has been used to any extent, has induced us to lay before our readers, in this number, several articles in relation to it, to which we invite their attention. As yet it has been used to a very limited extent at the South, but it is generally regarded such a valuable fertilizer, that the day is not far distant, we think, when its use will be very common.—We shall, therefore, with a view to the promotion of its preparation and application by our farmers, continue to lay before them, all such facts as may come within our knowledge relative to its preparation, or the advantages to be derived from its use; and if, in the mean time, any of them shall have, upon a fair trial, tested its merits, we shall feel grateful for the result of their experiments.

CORNSTALK SUGAR.

The interest which this subject seems to be exciting throughout the country, and our desire to afford our readers all the information we have been able to obtain, have induced us to devote much of the space of the present number to its elucidation, for which we are indebted to the very able report made to Congress by Mr. Ellsworth, the Commissioner of the Patent Office, and to the "*Southern Planter*," from which we obtain the directions of Dr. Naudain. From the facts already presented, we entertain no doubt that the production of sugar from cornstalks may be pursued profitably, and we trust that some of our enterprising planters will satisfactorily test its practicability, and give to the public the result of their experiments.

The work is foolishly executed by *many*, which might be accomplished by a few.

"BOOK FARMING."

The prejudice existing, particularly in sections of the country where little improvement has been made in the science of agriculture, against what is usually denominated "*book farming*," is but too common, and is one of the greatest obstacles to the introduction of an improved system of culture. This prejudice is very general at the South, where the universal practice has been to cut down and exhaust lands, without any regard to improving the soil, or any effort to increase its production by that enlightened system of culture which the science of agriculture teaches. Aware of the existence of this feeling, and the great difficulty of effecting an innovation upon a system so long established among our planters, we entered upon the duties of publishing an agricultural journal, not without a proper estimate of the barriers that would interpose. Happily, however, for the success of the experiment, the exhausted state of a large portion of the lands, and the poor reward their culture affords to the laborer, are likely to contribute as much, if not more, to the accomplishment of the great revolution we have so much desired, than any essays, however forcible or conclusive, that we could hope to present for the consideration of the planter: nevertheless we have deemed the following remarks of the editor of the "FARMERS' REGISTER," in which he enforces so ably and happily the benefits that science is daily contributing to the advancement and improvement of agriculture, so appropriate, and so well adapted to this meridian, that we could not deny ourself the pleasure to give them a place, and invite the careful consideration of the reader.

"All good farming is the result of science applied to the practice of the agricultural art; and of late years, the advantages which the latter has received from the former have been unexampled. The union of the two, in just proportions, makes the perfect farmer; it calls into action the energies of the mind; it leads to enlightened experiment and investigation; and when men's minds are brought into the exercise of their powers, advancement in any profession is the natural consequence. There is no art or profession that requires mental exertion more than that of the farmer; and the ridicule which has been bestowed upon what is termed book-farming, is becoming now, in a great measure, obsolete. Every experiment which has been made in agriculture, unless accidental, has been effected by experiment, by inquiry, by investigation. The soil is the material on which we all have to work; and in order to render this material productive, certain agents are to be employed. The application of these agents may vary according to circumstances, but the leading principles are the same in all countries. Let the intelligent cultivator cast his eyes around him, and he will perceive how much he is indebted to others for the success which crowns his labors. His implements are constructed in reference to correct mechanical principles; his manures are preserved and applied in conformity to known laws; every mineral ingredient which he combines with the soil, has been analyzed, and its virtues tested; and every just principle which governs him in his operations has been established by long and laborious investigation. With all the aids, however, which agriculture has derived from science, the practical part is still, with comparatively few exceptions, in a very rude state. Improvement extend at a very gradual pace, even with those means of diffusing information which the press offers to all. Witness the slow progress which has attended the use of marl in the south, which, but for the unceasing exertions of one individual, would even at this time be but little known; and which in fact continues to be unknown beyond the limits of his own influence. Lime also, a similar and no less powerful agent in the improvement of soils, has been scarcely used in the south, though the means of obtaining it are at hand in numerous sections of the country.

It is to elevate this depressed state of agriculture; to make the knowledge of one the common property of all; to excite a state of activity in the public mind, and to improve the condition of the agricultural classes, that renders the necessity of agricultural periodicals indispensable. It is very true, there may be much in such journals which may not be immediately available to the cultivator. But even then, their general influences and tendencies are beneficial. He is enabled to keep pace with the improvements of his profession; his mind is gradually directed to a higher standard than that to which he has been accustomed; he collects a general fund of knowledge, which will enable him, under propitious circumstances, to conduct his operations intelligently and successfully. He who is now satisfied to move along in the way his forefathers trod; to exhaust the soil without returning any thing which has been extracted from it; to dispense with the light which has been shed on his path by other minds, and to make no effort to enlighten others in return, is living for himself alone, and will leave no works to follow after him. Agricultural, as well as all other information, is now purchased at a cheap rate; cheap; compared with the benefits to be derived from it. Undoubtedly a man may burthen his mind with that which is purely speculative, as indeed he may reject every thing but what he has been wont to practice; but these are extremes, and the just medium lies between. It is, as we have said, the union of science and practice, the application of mind to the objects of daily pursuit, that makes the best farmers in our country. But for this union, what would be the condition of those farmers who are now most successful? What we learned from our fathers, was to impoverish the soil by severe cropping. They knew nothing of plaster and lime and marl; they paid little or no attention to grasses and manures; but drew every thing from the earth a kind soil would yield, without repairing the exhaustion which it suffered. It is obvious that we can no longer thrive on the same fields without great improvement in our husbandry. It is our manifest duty then to endeavor to restore what has been lost, or else it may hereafter be justly said of us, that we have eaten sour grapes, and our children's teeth are set on edge.

"The only effectual means that we are aware of, calculated to diffuse the information of which the farming community stands in need, are, legislative action in some form or other; agricultural schools, agricultural associations, constituted on correct principles, and agricultural journals. Legislative action, for any efficient purpose, appears to be out of the question. Our legislative bodies are too intent on politics, and politics is a subject of too absorbing a nature, to permit any thing not connected with it to claim the attention it deserves. Even the education of our youth, notwithstanding conventions have assembled, and numerous memorials have been presented to the legislature, and notwithstanding every man is convinced that the present system is productive of no positive benefit, and ought to be superseded by a better; even this great subject is almost utterly neglected, so far as legislative action is concerned. Agricultural schools would be an admirable means of doing good; but as long as their establishment depends on individual exertion, it is in vain to expect to see them in operation. Nothing available then remains but agricultural societies and periodicals.

"Of agricultural societies, we have elsewhere in this number of the Farmers' Register expressed our views. They constitute a powerful

agent by exciting the interest of the community and creating a spirit of emulation. But neither by them nor any other agent can extensive good be accomplished without the aid of the press. It is this which finds, or should find, its way into every man's house, and publishes to all whatever is interesting or useful."

For the Southern Cultivator.

HOME BEET SEED.

Mr. Editor—Many are of opinion that beets degenerate, and good seed cannot be raised at the South. This is a mistaken idea, and such is doubt it, let them try the following plan.—Have the ground well prepared, which is very important with all seed; plant at the distance of twenty or twenty-four inches in the drill, and thin to about six inches, keeping the ground loose by cultivation, and with a favorable season you will make fine beets. Then if you wish to make your own seed in hard times like these, and save your sevenpences, select one or two of your best beets, let them remain in the ground, drawing a little dirt around them so they be somewhat protected through the winter. In the spring remove this hill, and they will go to seed and do to plant the next spring. But if you wish still better seed, such as you buy in the stores, let the same beet remain in the ground and attend as before, and the second crop of seed will be as good or better than those usually kept in the seed stores. No mistake.

A Gardener.

Green County, Ga.

AGRICULTURAL SOCIETIES.

Within a few years, numerous agricultural societies have been formed in Virginia and the neighboring States. This fact clearly indicates that the spirit of improvement is progressing; for men seldom combine together, except on important occasions, and to advance objects which they deem to be nearly allied with the welfare and prosperity of the community. Agricultural addresses are also becoming more and more frequent, almost every society requiring the delivery of one from its presiding officer, at its annual meeting. Many of these addresses have been distinguished by great ability, and deserve to be diligently studied. They breathe the spirit of philosophical inquiry; record the progressive improvements which have been made in agricultural science; detail improved practices and interesting and valuable experiments; and thereby spread before the people a rich store of information and instruction, calculated to lead to beneficial results.

We would be very far from detracting from the merits of these various societies, as at present organized. They have done much good, and their influence will continue to be extensively felt. For the most part, however, we regard them as requiring one modification to render them eminently and permanently useful. The offer of premiums, it is true, excites emulation amongst the several candidates for distinction. A patch of corn, or wheat, or of roots, is cultivated with the utmost care, and a great product is obtained—ten times as much perhaps as under ordinary culture. Animals are fed and pampered for exhibition; and specimens of domestic manufacture, showing great toil and ingenuity, are displayed to admiring crowds. This is all highly commendable, and highly interesting.—These exhibitions, however, should rather be considered as the *ornamental* part of the institutions, under whose auspices they are gotten up. We would also recommend a *working* department. An example has been set by the agricultural society of Prince George county, which we consider to be worthy of all imitation. It is made the duty, by its constitution, of every member to institute one or more experiments; to conduct them with care; and at stated periods to report the results, whether favorable or otherwise. This plan opens the whole field of action. Farmers disagree, more or less, concerning almost every operation. Even the cultivation of our universal crop, namely, Indian corn, is the subject of great contrariety of opinion; some think it best to lay it by at an early stage, others contending for late working; some also being in favor of shallow culture, without disturbing the roots, and others of deep culture and tearing the roots to pieces. The cotton plant too, the great staple of the south, liable as it is to so many casualties and diseases, offers a fit subject of investigation for the combined action of societies. Whether a greatly increased production would add much to the net incomes of the planters is perhaps questionable; but improvements in the mode of culture, and the discovery of some protection of the plant against blight and other diseases, whereby a certain product might be attainable, would, at any rate, leave a considerable amount of labor to be directed to other objects. Such improvement and consequent increased production has indeed been already claimed by a planter in Alabama, who asserts that the crop is capable of being made to yield ten fold the usual average, without materially adding to the expense of culture. And in regard to wheat, which is the main stay of farmers of the middle States, it has become so uncertain of late years, that it strongly invites to a course of judicious experiments. Without doubt, the most formidable evil to which it is liable is the rust. Farmers individually, as well as societies collectively, should use every exertion in order to discover some means of guarding against its ravages. That these means are within the reach of those who diligently and intelligently seek after them, cannot be reasonably doubted. Our climate has experienced no essential modification; seed time and harvest remain the same; but the constitution of our soils may have undergone some material change under a long course of culture. The remedy therefore that would seem at least in part, to be indicated, is to restore to their constitution those ingredients which are best adapted to nourish and sustain the grain.

So also of other crops, from the greatest to the least. It is to enable cultivators to attain some uniformity in their managememt; to collect information on numerous unsettled points; to test the value of new varieties of plants; to ascertain the best mode of making, preserving and applying manures; in short, to throw light upon every thing, and every operation pertaining to agricultural and rural economy—that such a course of experimenting recommends itself to the practical farmer. And not the least beneficial effect which such a practice would produce would be its tendency to call the *mind* into action, and to induce habits of observation and inquiry.—*Farmers' Register.*

FARMING IMPLEMENTS.

The remark we have somewhere met with, and it is very probably true, that the arts and sciences have made greater advances within the last half century, than in the eighteen centuries preceding. Among other improvements those which have been made in the implements of husbandry are very great, and they are still in rapid progress. There is scarcely an implement used by the farmer forty years ago, that is not now more or less improved in its model and construction, and a great many new and almost invaluable implements have been added. These improvements not only abridge manual labor to a highly important extent, but they enable the farmer to do his work better. A number of examples in point might be given, but we need only mention the improved plough and harrow, the cotton gin, &c. It is manifest that the community of farmers in which improved agricultural implements are introduced and employed, enjoys decided advantages over that in which the old, unwieldy, inconvenient implements are still made use of. The one is supplied with a certain ready force and a skill in mere machinery, which the other must supply (if supplied at all) with increased wear and waste of human sinews. There is perhaps nothing, therefore, so well calculated to promote the agricultural prosperity and increase the agricultural wealth of a country, as the introduction of improved implements of husbandry.

We would respectfully suggest to our Agricultural societies, generally, to give something more of their attention to this subject. Premiums are not so frequently offered as we should be pleased to see, for the best ploughs, the best harrows, clover machines, hemp knives, corn crushers, &c. In the northern States, this branch of improvement has not been overlooked, but in some of the New England States, great emulation has been excited in the way of agricultural machines by the liberal premiums of Societies, and the patriotic energies of individual agriculturists. The consequence is, a very decided improvement in all farmers' tools, and none more than the plough, with which regular tests are made in ploughing matches, superintended by society organizations.

Dairy Secret.—Have ready two pans in boiling water, and on the milk's coming to the dairy, take the hot pans out of the water, put the milk into one of them, and cover it with the other.—This will occasion great augmentation in the thickness and quality of the cream.—*Al. Cult.*

AUGUSTA MARKET.

Tuesday P. M., March 28.

Cotton.—The market, since our report of Tuesday last, remained in a very quiet state till after the arrival, on Saturday, of the news per the Columbia, at Boston, bringing Liverpool dates to the 4th instant, showing a farther decline of ⅛d. in that market; since which there has been some more activity in our market, and sales have been made at ⅛ to ¼ cent decline.—We quote 3½ to 6 cents as extremes—principal sales 3¾ to 5¼ cents.

Exchange.—The rates for Exchange are without change, being at par on all points north and east of us. Central money 25 @ 30 ℔ cent discount. Alabama notes 20 @ 25 ℔ cent discount. Other depreciated notes are difficult of sale at any price.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, invariably in advance. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

Advertisements pertaining to agriculture will be inserted for one dollar for every square of twelve lines, or less, for the first insertion, and seventy-five cents per square for each continuance.

☞Post Masters are authorized to receive and forward money free of postage.

☞All communications must be post paid.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., APRIL 5, 1843. No. 5.

EXTRACTS FROM THE ADDRESS OF H. COLMAN.

DELIVERED BEFORE THE AGRICULTURAL SOCIETY OF MONROE COUNTY, NEW YORK.

The improvement of agriculture may be said to comprise two objects; first, the improvement of the art of cultivation, and second, the improvement of the condition and character of the cultivators. The improvement of the former is a small matter compared with that of the latter; the improvement of the latter, understood in its best sense, must essentially aid the improvement of the former. * * * *

1. If we apply this test to our present husbandry, we shall be compelled to acknowledge that it is far from having reached the perfection of the art. If we look first at the amount of products, even in this favored region of western New York, the average yield falls far below the possible yield; and by the possible yield, I mean not a mere theoretical or speculative production, but that which has actually been accomplished. Of wheat, some of the most intelligent farmers state that the average yield does not exceed, and this in the most favored districts, twenty bushels to the acre. Now, I have known thirty bushels to be taken on large fields, forty bushels, fifty bushels, and upon one large tract sixty-four bushels per acre. I speak now of home production, and not of foreign countries. In this matter, likewise, there is little reason to question these statements, as the wheat crop is easily, and almost always measured with exactness, in the half-bushel or by weight; but reports of very large crops of Indian corn, are always distrusted by the sceptical, on the ground that the corn may have been measured in the ear, or only a portion of the field may have been measured, and the rest made matter of inference; or no allowance has been made for shrinkage. In respect, however, to Indian corn, making all the abatements for error that the incredulous may require, it will appear that such yields have been obtained as should make the farmers, who are satisfied with the meager crops usually obtained, at least open their eyes, if in truth such men have any eyes to open. I have been exceedingly surprised, when informed by farmers in western New York, whose good judgment and intelligence cannot be distrusted, that the average yield of Indian corn does not exceed 25 bushels to the acre. Now fifty bushels are not an extraordinary crop. I have known seventy-five bushels per acre to be the ordinary yield of one farmer, whose cultivation was extensive. I have had authentic information of the crops of Indian corn of one farmer, having for years exceeded one hundred bushels per acre, shelled and measured accurately in the half-bushel, in the spring. I have known, upon the most undoubted testimony, one hundred and twenty-eight and one hundred and thirty-two bushels per acre, produced in localities which seemed most inauspicious.

In respect to grass, the crop of hay does not probably average more than one and a half ton per acre. Now I have known many crops of three tons per acre on extensive fields; and in one case I knew more than twenty-nine tons to be taken in the same year in two cuttings, upon six acres of land. In respect to potatoes, the yield is probably not more than two hundred bushels per acre. I have produced crops of more than four hundred and eighty bushels, and have known repeatedly seven hundred bushels per acre, and in one instance, at the rate of more than twelve hundred bushels per acre.

I might instance other crops; but it is sufficient to have referred to these, to show that our husbandry in general, in respect to its productiveness, is far inferior to what it may be. In many cases our soil is not inferior to any which the sun shines upon. There is in our climate no hindrance to the highest measure of production. The large crops to which I refer, are the result of skilful and superior cultivation. They do not come by chance. They show what skill and labor can effect. It will be said that they involve an expensive cultivation, but in every case within my knowledge, they have rendered an ample return for all the labor and expense incurred. An observing farmer will perceive that in most cases a few extra bushels in the yield constitute all the profit of a crop. Thirty bushels to the acre, may barely pay the expenses of cultivation; but fifty bushels, without any increase of land, or labor in planting, cultivating or harvesting, may leave a clear profit of twenty bushels per acre. It will be said that such cultivation exhausts the soil. It does not exhaust the soil any more than poor cultivation exhausts the soil; and it is followed with this remarkable difference, that it affords the means of enriching the soil and restoring its exhausted energies, which poor cultivation does not. Who ever heard that a farm became exhausted by good cultivation? Whose farms are in the best condition; the farms of those who grow the poorest, or those who raise the largest crops? Farms may be exhausted by growing the same crop too often, in immediate succession on the same land; by carrying off the products from, instead of consuming them on the farm, and thus returning nothing to replenish the soil in the form of manure; but under a wise and skilful and liberal husbandry, it would be difficult to find a country exhausted of its fertility by production. Look at our immense forests, and calculate what an enormous amount of vegetable matter is contained in the timber upon an acre of ground. But is the soil impoverished or enriched by it? Is not the vegetable pabulum, the food of plants, constantly increased by the growth of this heavy timber? Would land become more rich by leaving it uncovered and without plants? Does a naked fallow enrich the soil? A fallow may benefit the farmer by the destruction of noxious weeds. The land is benefited by being stirred, and exposed to the influence of the air, and dew, and frost, and rain. But would a fallow kept constantly clean, and extended even through a series of years, do any thing to increase the fertility of the soil? Undoubtedly, a large proportion of the carbon of which plants are composed, of the food of plants is derived from the atmosphere, of that which is above the ground, and that which is within the ground; but as undoubtedly this is received only through the organization of the plant, through its leaves and stem. The living plant itself decomposes the atmosphere, and appropriates to its own growth and nourishment that which it requires. So, likewise, it decomposes the vegetable matter already existing in the soil, in a state of decay, and recovers the food, which, in the dissolution of a previous vegetable growth, has there been stored up for it, and is held ready for its use. With the exception of the salts or the mineral substances, which are found in plants, and which in any case constitute comparatively a very small proportion of their substance, they derive all their food and nourishment from the air, either directly or indirectly; directly through the leaves and stems, by a process of absorption well understood, in which the elements of the air are decomposed, and its carbon appropriated; and indirectly through the decayed vegetable matter or humus of the soil, itself the product of former vegetable growth.—So far then from vegetable production serving to impoverish the soil, it is the means of increasing its fertility. In proportion as we cultivate and enrich our lands from their own resources, under a judicious arrangement and management, they become constantly more and more fertile. By the beneficent constitution of Divine Providence, the earth, while it contributes to the support of man and beast, is designed to become more productive, or to keep up its richness, from its own activity. It is like the fountain of true charity, and beautifully emblematical of the Divine beneficence; the more it expends the more its abundance increases. It is like the human mind; the more active it is rendered, the more its powers are invigorated; the more it does the more it can do; and the more its treasures are poured out, the more its fullness is enlarged. The great object of the art of agriculture is therefore yet to be achieved. What has been done once, can be done again. There is no monopoly of power in this case.—Nature is uniform in her laws and operations. It is an old saying, that "fortune favors the brave;" that is, men find their powers increased with their activity; according to the Latin proverb, "they are able because they believe themselves able." In many respects they command fortune. Taking advantage of the simplest of nature's laws, and using her forces as she designed they should be used, she is never wanting on her part, but seconds every effort for improvement; and the more readily and cheerfully as these efforts are the more spirited, energetic and determined. If any man has raised one hundred bushels of corn, or sixty bushels of wheat to an acre, who will pretend that it cannot be done again? No farmer, who deserves to be called a farmer in the highest sense, and to take rank among the noblest of this nature's nobility, the lords of the soil, ought to remain content until he has done it. When he has accomplished this, then he should not be satisfied until he has done even much more than this. There is undoubtedly a limit beyond which we cannot advance. All human attainments are necessarily finite. But who knows where this limit is?—Who ever went so far as to be certain that he could go no farther? The difference between that which cultivation has produced already in some hands, and that which is ordinarily produced, is very great, and sufficient to occupy the enterprise and ambition of most farmers, for a long time to come. But let them make the attempt to do all they can do, or rather all that can be done. They may not succeed at once. Few men succeed at once in any great enterprise. But let them try again, and again, and again.—If, after doing their best, they fall short of the goal of their hopes and expectations, yet there is a great pleasure in trying. There is a great satisfaction to a generous mind, in the mere pursuit of a good and useful object. An immense benefit comes to the community from an exam-

ple of intelligent and persevering exertion. Let there be a generous ambition and a constant stimulus to enterprise, in all the departments of human industry and activity. When the heart beats, the impulse is felt throughout the frame; and you cannot quicken the stream of life in any one part, without accelerating the circulation through the whole body. Go on, then, trying to do better and better. The farmers have been too often the sport of the rest of the community for their sluggishness, their indifference to improvement, and their incredulity in respect to what has been done, where any thing extraordinary has been effected. Injustice has often, but not always, been done to them in this matter. They should shake off this apathy. They should wake up. While every other art is advancing in the career of improvement, almost with the speed of a locomotive engine, they should whip up their team, and not be distanced in the competition. There is a beautiful circumstance connected with agricultural emulation. In many of the pursuits of life, one man gets rich by making another man poor. He climbs the ladder by putting his foot on another man's shoulder; or, he builds his own dwelling out of the fragments of his neighbor's, which he has undermined. This is often a crying injustice, and inflicts many bitter mortifications, or arouses vindictive and tiger passions. Emulation in agricultural improvement enkindles no such baleful fires. A man can make no improvements in husbandry, without at once extending the knowledge and advantages of them to others. The enlargement of capacities of the soil, and every increase of its productions, confers an immediate benefit upon the whole community.

* * * I proceed to speak of the other subject suggested; that is, the improvement of the farms themselves. It will be seen, from what has been said, that agriculture is a great art; and that its improvement demands the highest exercise of the highest powers of the mind. If there was ever a subject presenting food for intellectual inquiry, that subject is agriculture, involving, as it does, the most subtle operations, and the deepest mysteries of nature. It is the mind which constitutes the true dignity of our nature. Without it, man would be a mere machine; with it, he becomes a divinity. It is for the farmers to come to a knowledge of the true character of their great calling, and place it where it belongs, among the liberal professions, and among the most exalted of sciences. Formerly, whenever there was a lame or deformed child in the family, it was thought he would do for a tailor or a minister; and if he were a dunce or a blockhead, he would answer for a farmer. These prejudices are gone, and that stock is nearly worked out. Agriculture is assuming its proper place among the pursuits of men; and yielding to none under heaven in usefulness, in honesty, and intrinsic respectability, let us seek to prove, that while it presents objects to call out and interest, it is every way worthy of the application of the most improved talents which ever fell to the lot of man.

Agriculture is not a mere physical effort or labor. It is a science. It is a branch of intellectual philosophy; and its improvement and perfection, if ever it is to reach perfection, are as dependent upon the application and instrumentality of mind, intellectual perception, intellectual skill, knowledge, I will add genius, as any art or science, which is the subject of man's power or attainment.

I am aware that this is not the light in which it is usually regarded. The public sentiment in this respect needs to be reformed and strengthened. Justice has not been done to this art. It is encouraging to belive, that in this matter, public opinion is undergoing a favorable change. I am anxious to see agriculture occupying the place among the humane, liberal and intellectual arts, which belongs to it. But if it would reach and maintain that station, it must prove itself deserving. It may be carried to the throne by acclamation; but, as the public judgment is constantly becoming more enlightened and severe, it cannot maintain its ascendancy unless it is worthy of it. The laurels will be plucked from its brow, if they are not the rewards of merit.—It can prove itself worthy to rank among the liberal and enlightened arts, only by becoming itself liberal and enlightened. Study, inquiry, reading and knowledge, are as much demanded for the advancement and perfection of agriculture, as for that of any art or science. We may expect from science, inquiry and the efforts of genius, the same advantages here as in any other place or objects where they may be applied.

* * * * * *

I proceed now to the consideration of a means of elevating the agricultural profession of more importance, because of much more efficient influence, than any to which I have referred; and that is education, knowledge, intellectual improvement.

I have already said that the glory of man is his mind. If his animal nature is curious, and wonderful and beautiful, his intellectual nature is transcendent and divine. This places him at the head of the animal creation. In his mind as in the seed lie the undeveloped elements of moral growth, and the secret sources of that energetic authority which subjects the most powerful elements of the physical world to his sceptre, and makes him "the monarch of all he surveys." In an art, involving many of the most wonderful operations—and agriculture is that art—dealing in the most subtle agencies in nature, and presenting even to the casual observer, in cultivation and in vegetable and animal growth, a succession of miracles, where is there moroe ccasion for the most subtle inquiries of philosophy?

To the careless observer the deposite of a seed in the earth, its germination, its after cultivation, its progressive growth and its ultimate maturity, are matters of such every day occurrence, that they create no surprise, and are seldom remarked. But they are all replete with wonders, which in their solution have hitherto defied to a large extent the most subtle searchings of the most subtle minds. Where does life repose in this dried kernel, so small and to all appearance so utterly inert? What secret agency swells and protrudes the germ? By what power does it force its way above the surface and gradually expand its leaves, and put forth its flowers, and mature its fruit? How and where does it gather and assort, and at its pleasure use or reject the various materials which go to form the stem, the leaves, the flower, the fruit? How does it construct its exquisite cells and pierce its delicate tubes, and elaborate its juices, and drink in the subtle gases that float around it, keeping that which it needs, sending back that which it does not need, doing that by its own spontaneous energy, which the chemist deems the highest triumph of his skill, and framing its wonderful organism, and compounding its peculiar odors, and mixing in exact proportions its beautiful colors; and all this while, be the situation or soil, the appliances or manures, what they may, remaining true to its kind, so that the grasses do not change into the umbelliferous plants, nor the bulbous roots transform themselves into the cereal grains? Beyond all question all these operations go on according to fixed laws, perfectly simple in their operation, if we could but understand that operation;-and no more the effect of chance or accident, or direct interference of the divine artist than any other of the regular operations of the material world. But what are the influences and effects of seed and soil, of heat and light and electricity and gravity, of dew and rain, and air, and manure, and culture, by what power exerted, by what circumstances controlled, all these are matters for philosophical inquiry, and as yet can scarcely be said to have been approached. The rearing and improvement of live stock, and the whole subject of comparative anatomy and animal physiology, are matters likewise coming directly within the province of the farmer, full of food for the inquisitive mind, and opening a wide field of inquiry. Is education then of no value to the farmer? Has knowledge no use to him? Is his profession a matter of mere servile and animal toil? Has the mind no work to perform here? Is this art to form an exception to every other?

How far is the art in any country from having reached the highest point of productiveness? Where and when, indeed, has the actual capacity of a single acre been tested? Is there no room for inquiry, for the exertion of the highest powers of the mind to determine this point?—The same remarks apply with equal force to the rearing and management of live stock. Any man who compares an improved Durham short horn, or a full-blooded Merino or Dishley sheep, with the common stock of the country, and does not perceive how much has been effected by the exertion of the highest measure of intelligence and skill directed by science, and how much more is yet to be hoped for by renewed and continued efforts, seems doomed to a hopeless stupidity.

If at the same time we look back to what has been gained in the actual increase of the products of agriculture, we shall see equal reasons to acknowledge the advantages derived from the application of mind to this art, and to take courage in view of what may hereafter be gained. I have already touched upon this subject. Half a century ago, fifty bushels of Indian corn to the acre would have been regarded as an extraordinary yield. A crop of a hundred bushels is not now uncommon, and more than one hundred and seventy have been produced in this State. In Scotland a few years since, thirty bushels of wheat would have been beyond the average yield even of the best cultivation. Under a system of under-draining and subsoil ploughing, sixty are not uncommon. It is not long since the system of leaving half the ground fallow was deemed indispensable, in order to recruit the exhausted lands; now, by a judicious rotation, alternating white and green crops, the land is kept uninterruptedly in production.

Education may be considered in two aspects; first as general, embracing all the common subjects of reading and inquiry; second as specific, limiting itself to the particular objects of the agricultural art. Both are equally conducive to the respectability of the profession. We see every where, what an influence and standing the high cultivation of the mind gives to every man who has it in our community. No official station, no mass of wealth so elevates a man; and even if we were cursed with the aristocratic distinctions which prevail in other countries, such is the spreading influence of intelligence, that the cultivation of the mind would enable the man to overtop them all. To attain excellence in any art, the principles of that art require to be made the objects of specific inquiry and study. But giving to these considerations all the prominence we may, success in any art or science will essentially depend, not merely and not more, upon the knowledge of the particular principles or elements connected with it, than upon the strengthening and enlargement of the mind by general knowledge.

We must likewise observe an obvious distinction between the knowledge of the practice of, and the knowledge of the principles of an art. Men may thoroughly understand the principles of an art, without knowing any thing of its manipulations. The philosopher may investigate and explain with the greatest advantage to the common farmer, the principles of vegetation, and the operation of manures, without himself having even so much as reared a single flower, or stuck even a garden spade into the ground. In order to a successful practice, the art must be learnt as well as the science, the execution as well as the theory. The best prospect of success is when they are united; when science directs the application of art, and art in its turn demonstrates the lessons, and shows the proper qualifications and necessary limitations of scientific principles.

To render the profession as respectable as it

may be, they should be combined. The farmer's vocation in this respect presents singular and extraordinary advantages. His seasons of relaxation from toil in our favored climate furnish enviable opportunities for reading and inquiry. Besides this, none of the labors of the farm, excepting where they are excessive, require any intensity of application or any abstraction of mind, which would interfere with the most active exercise of the intellectual powers on subjects quite foreign from his immediate occupation. The farmer may commune intimately with nature even when bending over his hoe; he may talk reverentially with God about his wonder-working providence from between the handles of his plough; and he may often in his fields hear the deep voice of a divine philosophy speaking to his soul, as the shepherds heard a message from Heaven, while they were counting the stars and watching their sleeping flocks upon the plains of Babylon.

MANURE.

Comparative benefits of Manure turned under or applied on the top. By Dr. W. J. Dupuy.

Your society requires of each member to contribute something in the way of experiment to advance the great cause of agriculture. Although just recovered from a severe indisposition, I am, nevertheless, unwilling to be a delinquent, though I must urge that as a reason for the very brief and summary way in which my communication shall be made.

I proposed at your last meeting to give the result of an experiment, the object of which was to establish the comparative merits of fallowing in putrescent manures with marl, and of the application of similar manure, on the surface, after the fallowing in of marl.

During the summer of '41, I marled an exceedingly poor piece of land, at the rate of 250 bushels to the acre, averaging from 40 to 50 per cent of carbonate of lime. I should suppose the land would not produce one barrel of corn to the acre, in its unimproved state. During the month of November, I began to haul out, as I found leisure, with a pair of carriage horses, good putrescent manure, from my lot in town, I should say about the same quantity to the acre, of which marl was applied. In the month of January, the marl and manure having been scattered, the field was fallowed. I will say, however, that up to this time, not more than half the field had been manured. The manuring progressed, without any delay, after the fallowing, upon that portion which had not been manured, though fallowed with the marl as before stated. I was not able to procure manure enough of the same richness to extend throughout the field, though enough to extend a considerable distance beyond, and contiguous to that which was turned under. The last of the field was manured in the spring, with the best rotted manure which I could procure from my winter farm-pen—all spread broadcast. The whole field was cultivated alike. Throughout the whole season, a marked difference could be seen to the line, through the field, in favor of that portion where the manure was turned in at the time of fallowing; that which was top-dressed in the spring, with the farm-pen manure raised during the previous winter, being inferior to either. And here I would remark, that the theory of the decomposition of manures, and the necessity of applying them in a partially decayed state in order to secure the dissipating gasses, has, in my opinion, led to the opposite error of applying them before they are sufficiently decomposed. Such has been the result of my experience for years. It may perhaps be my misfortune in not knowing the precise state when the manure should be applied.—Though, in fact, I have been able to get very little from my winter farm-pen in a suitable state, (according to my notion,) to apply during the spring, notwithstanding it has been my practice to heap it in February, which very much facilitates the decay. With these views, I have been compelled to let a great portion of my farm-pen manure remain for summer application.—On this subject I should be glad to be properly informed.

I regret that I am not able to state to the society, in something like definite terms, the comparative product on the different portions of the field, as I had proposed. It will be remembered, that in August there was an easterly storm, which laid prostrate the corn. Notwithstanding this, however, (although it might have been attended with some difficulty,) a measurement could have been made, but in a journey which I took about the time of gathering corn, my hands had, before my return home, gotten in the whole field, which put it out of my power to make the comparison. If, however, I should venture to guess at the comparative result, I should say that that portion of the field which had the manure fallowed in, produced four barrels, while that which had the top dressing of the same kind of manure did not produce more than 2½ or at most 3 barrels.

While I am on the subject of this communication, I would state a few facts which may not be uninteresting to the society. In May or June, 1841, one of the auctioneers of our town stopped me to propose to let me have some spoiled shad, then lying at his door, provided I would take them away in a given time. Having obtained from the police master, (who was about to impose a fine for such a nuisance,) an extension of time sufficient to enable me to remove them, I set to work, and in a few hours carried to my farm 17 barrels. These I deposited in one pile in the field which is the subject of this communication, and covered them over well with marl, supposing that they would be in a properly decayed state to spread as manure for the corn this year. Indeed, from the offensive character of the fish, I had supposed they would be in a condition to fallow in during the winter. However, during that whole summer and winter, and subsequent spring, (1842,) I was surprised to find, from the occasional exposure made by the scratching of dogs, that the fish were not only *not* decayed, but that they even smelled sweet.

Even down to the latter part of the last summer, some exposure showed that they were still sound. Whether they will be suitable manure for my crop of oats next spring is still to be seen. From the prominence of the bulk at this time, I fear they will not, but even if they should, there will be a space of nearly two years necessary for their decay. Their state of preservation may be judged of when I state that it was often a subject of regret with my negroes, that such fine fish should be thrown away, and I believe, but for my restraints, they would have used them frequently for food, being used to fish as a diet, and very fond of them.

There are several reflections to be drawn from the facts just stated. It is evident that marl or carbonate of lime is antiseptic, and purifying in its effects. At the same time it may be a fact that fish are slower in their decaying and decomposing process than most other animal substances. If marl or lime arrests the decay of substances intended for manure, is it the most suitable thing with which such substances should be enveloped and brought in *immediate* contact, the object always being to procure as speedy decay as possible?

That the marl has the faculty to arrest and fix, as it were, for useful fertilizing purposes, that portion of the decaying matter which would evaporate and otherwise escape, I do not doubt; but perhaps it would be better to let the marl be on the outside of such a bulk as has been described, so as to arrest this evaporating portion as it would escape on the exterior, and at the same time not interfere with the decomposition which should go on in the interior. I would remark, however, that I have not observed the same slow decay where cows and horses have been thus enveloped with marl; thereby leaving the impression that there is something peculiarly slow in the decay of fish. With these views, I would say that it would perhaps be better to cover such a bulk first with earth or vegetable matter, which would not interfere with the decay, and then the superincumbent covering of marl.

THE HESSIAN FLY.

A few years ago I commenced the business of farming, more for the purpose of a pleasant relaxation from professional life, than with the hope of gain; and my fondness for the occupation has led me into many experiments and much close observation of things pertaining to the subject of agriculture; and I do not know but it may lead me to trouble you and your readers occasionally with the result of them. If I supposed I could add any thing to that spirit of enterprise, which you and others seem to have awakened among the farmers of this day, or suggest an idea which a practical farmer might turn to a valuable account, I should feel gratified. In my pursuit of information on this subject, whenever I have found an opinion with regard to a fact, a cause or an effect, to be generally entertained by farmers whose attention has been called to the subject, I look upon it as entitled to respectful consideration, even if it does not at once command entire belief, it is worth a book of philosophical theory.

As you know, this is a wheat growing district, and our farmers may be supposed to know something of whatever concerns the cultivation of that grain. They entertain an opinion with regard to the Hessian fly and its appearance, which is natural, and which my own observation has convinced me is in accordance with the truth. It is a big-bellied insect, which makes its appearance in the fall, when the mildness of the weather will admit, especially at that season called *Indian summer*, and its coming is easily discovered; when it alights upon the ground, it divests itself of its wings and assumes the appearance of a large black ant, and from its hurried manner, seems to be seeking a place of deposite for its egg; this it soon finds, either in the crevices of the ground, under a clod, or in the wheat plant; and not always in the latter as is sometimes supposed. After the egg is deposited, the insect seeks shelter for itself in the ground, where it remains during the winter; and either it or its progeny appears again in the spring, to go through the same work of destruction. The opinion is entertained by some, that the egg deposited in the fall remains to be hatched in the spring—but not so; nature makes better provision for her creatures, than to cause the egg to be laid in the fall, exposed to the frosts of winter, to be hatched in the spring. The egg laid in the fall does its injury to the grain then, or not at all: its effect is then perceptible; and it is the reappearance of the fly in the spring which repeats the evil. My observation has convinced me that this is the Hessian fly; and that there is a most infallible remedy for its destruction—as certain as it is simple—the use of the roller. A very little care and observation, at that season of the year when the farmer expects its approach, will discover its presence; and then is the time, whether it be spring or fall, to roll the wheat fields; the weight of the roller not only destroys the insect itself, whose size and shape prevent escape, but it destroys also the tender egg, whether deposited in the wheat plant or elsewhere. I have used the roller for six years, and I have never seen the effect of fly in my wheat, while crops around me have been partially destroyed by it.

W.

Farmers' Cabinet.

To Wash Woolen Goods.—The art of washing woolen goods so as to prevent them from shrinking, is one of the desideratum in domestic economy worthy of being recorded, and it is therefore with satisfaction we explain this simple process to our readers. All descriptions of woolen goods should be washed in very hot water with soap, and as soon as the article is cleansed, immerse it in cold water; let it then be wrung and hung up to dry.—*Southern Planter.*

LIEBIG'S ANIMAL CHEMISTRY.

The ancients held that all bodies were composed of fire, air, earth and water, which they called elements. The chemists of the present day enumerate fifty-five elements. Of these only a few enter into the composition of organic beings. Into the texture of plants and animals minute portions of lime, iron, silex, soda, potash, sulphur and phosphorus enter; but it is carbon, nitrogen, oxygen and hydrogen, that constitute the main bulk of their solids and juices. These last are the alphabet, so to speak, out of which the beautiful volume of the living world has been composed. Widely as plants and animals differ in outward show from the atmosphere they breathe and the soil in which they are fixed and on which they tread, they present on analysis no element which is not found in the mineral kingdom. It may well excite surprise that the blood, mantling in the cheek of female beauty, and the brain which gives manifestation to the mind of the orator and poet—that the muscle of the herculean frame, the viper's venom, the food that nourishes, and the vegetable poisons that destroy, the nectar of flowers and the noisome exhalation of marshes, all, however varied in form or opposed in quality, consist of these four elements in endless combinations—all derive their shape and strange diversity of attributes from varying proportions of oxygen, carbon, nitrogen and hydrogen.

Animals and vegetables agree, in deriving their existence from parents, in growing from small beginnings to a determinate size, and then yielding up the living principle, and mouldering into the elements from which they grew, by which they are easily distinguished from the inorganic matter which constitutes the mineral world. Animals grow by imbibing oxygen and eliminating carbonic acid; vegetables, on the other hand, absorb carbonic acid, retain its carbon, and emit the oxygen. They both live in the atmosphere, which is equally indispensable to either race, but each derives support from matters given out from the other. They would alike perish in an atmosphere of carbonic acid, but while this gas is exhaled continually from the lungs and breathing pores of every animal, it is greedily drunk up by the green vegetable, and aids in its nourishment and growth.

Liebig has written with singular ability on the functions of both classes of vital beings.—His admirable treatise on vegetable physiology and agriculture has been repeatedly noticed in our paper, and we propose now to give an outline of his theory of animal chemistry.

A few years ago, very little was known of the chemistry of organic beings. Analysis, it is true, had been effected of many animal and vegetable products; and isolated facts, the value of which was not appreciated, were scattered over the pages of writers on physiology and chemistry. A rude attempt was made at an early period in the history of these sciences to explain upon chemical laws some of the functions of animal beings, but these speculations, for the most part, were eminently and even ridiculously abortive. Where the early chemists hit upon the right track they were soon lured from it by the absurd philosophy of their times, and their best efforts were but slight approximations to the truth. But their labors multiplied the materials of the science, and out of the shapeless mass of observations which has been steadily increasing, the beautiful system of Liebig has emerged.—Since the time of Dr. Black, some of the great minds in every period have been busy at work upon the foundations of animal chemistry, and the science has at last assumed a shape which promises to be enduring. The honor of rearing the edifice will generally be ascribed to Liebig, but this is not entirely just, for, on many points, the most that he can claim is the credit of having worked into a system facts which others had established. This, indeed, was a great work, requiring a genius of a high order; nor is it the only merit which belongs to this author. He has verified results, in numerous instances, by repeating experiments with the utmost care and precision; and he has added by his original researches many important facts to our stock of knowledge on several subjects connected with the functions of living beings. In his hands the materials have been classified and arranged, and have assumed the character of genuine systematic science. We have no hesitation in saying that he is one of the first philosophers of the age, and that the present, like his former work, will compare in logical clearness and original speculation with any that has been produced in modern times.

The power in animals of maintaining an equable temperature under great differences of exposure, is one which has engaged the attention of physiologists since the earliest ages. A man, it has been proved by the most repeated observations, preserves the natural heat of his body whatever may be the temperature of the climate in which he lives. At Palermo, or Algiers, where Fahrenheit's thermometer, in the shade often rises to 100 degrees, the temperature of his blood does not grow warmer than his hyperborean brother, who is exposed to an atmosphere that frequently sinks the thermometer many degrees below zero. What makes the case still stronger, men have often been shut up for a short time in a room, the air of which was heated far above the boiling point of water—to a temperature high enough to broil a beef-steak and boil vegetables, without suffering any decided rise of their own temperature. These are curious facts, illustrating forcibly the independent temperature of animals; and this remarkable function is one of the problems to the solution of which Liebig has devoted a considerable portion of his work. With Dr. Black, Lavoisier, Crawford and others, he regards respiration as a process of combustion, and as we warm our apartments by burning coal and wood, so we keep up the warmth of our bodies by burning portions of our food, which we take in as fuel. The animal body, according to this doctrine, resembles a furnace—the food corresponding to the fuel, and the oxygen of the atmosphere serving, as it does in the furnace, to consume the fuel and evolve heat in the process. Lavoisier has shown that a man of ordinary size, and in perfect health, consumes more than seven hundred pounds of oxygen in the course of the year, without gaining in weight. The man, during this time, has been taking food every day, and Liebig proves very clearly that a large portion of it must have united with the oxygen to form the carbonic acid, fifty thousand cubic inches of which are daily exhaled from the lungs of an adult. Now the conversion of carbon into carbonic acid is essentially a heating operation. It never takes place without the extrication of heat. The union is rapid in our fire-places, and the quantity of caloric emitted in a given time is very great; but the amount of heat generated by the combustion of a specific quantity of carbon is a fixed quantity. It is evolved slowly from the mass of fermenting vegetable matter, from the malting grain, for example, and from the heap of half-cured hay, but the number of degrees of heat thus given out is not less, for the quantity of carbonic acid formed, than if the combination had been the work of a few moments.

A man in good health, and taking moderate exercise, consumes, according to our author, nearly fourteen ounces of carbon daily, which escapes in due time, as carbonic acid, through the lungs and skin. For the conversion of so much carbon into the acid, thirty-seven ounces of oxygen are necessary, and in this union, which takes place in the body every four-and-twenty hours, 195,531 degrees of heat must be liberated—an amount sufficient to cause 68 lbs. of water at 32 degrees to boil; or to heat 184 lbs. to the temperature of the human body. If to this, the heat evolved by the hydrogen of the food, during its conversion into water by oxidation within the body, be added, we shall find the quantity amply sufficient to explain the uniform temperature of the human body.

But, in order to maintain this constant temperature, the supply of food and of oxygen must vary with the changes of atmospherical heat and cold to which the individual is subjected. He must take more food in cold climates than in hot, and more in winter than in summer, and his food must also be of a richer quality. And this is the case with the inhabitants of high northern latitudes. The Russian, amid the snows of the arctic circle, devours the raw flesh of the deer, and drinks its warm blood as it flows from the body; and the Esquimaux will eat ten pounds of flesh and perhaps a dozen tallow candles into the bargain, daily, without the slightest fear of indigestion. The people, on the contrary, who inhabit a climate but little below the temperature of their bodies, subsist chiefly upon fruits which contain a small proportion of carbon. At the north, such fruits could not be matured, nor would they be suited to the wants of the inhabitants. It is animal food, and that of the fattest quality, that they need to supply their systems with the requisite amount of fuel. Children, for the reason that respiration in them is more active than in adults, require to be fed oftener; and birds, having large lungs in proportion to their bodies, die of hunger in as many days as it takes months to starve serpents which breathe slowly and consume little oxygen. The animal heat of the two tribes of creatures is correspondent. That of birds is higher than the temperature of man; that of the reptile is but two or three degrees above the temperature of the surrounding atmosphere.

The food of animals, therefore, performs a two-fold office—it contributes to the nourishment of their bodies, and it furnishes the fuel by which animal heat is developed. This is one of the most striking and original of Liebig's doctrines, according to which the aliment of animals consists of two classes of substances, destined to perform altogether different purposes in their economy. The first he calls the *nitrogenized* elements of food, or *the plastic elements of nutrition*, which go to make blood, and execute the various offices of growth and reproduction; and the second *non-nitrogenized* elements, which do not contribute to the nourishment of the body, but are consumed in the production of animal heat. Milk, which is the food of the young animal of so many species, contains both elements. The caseine, or cheese, is the portion which nourishes; it contains the materials for making blood, for the formation of bone, and the other functions of its immature system, whilst the sugar of milk, and the butter supply it with fuel. In wheat, and other grains of this class, as also in the potato, though not to an equal extent, the same admirable combination exists, and these are the chief articles of food for man and for his domestic animals, in nearly all the temperate regions of the globe. The nutritious principle is contained in the gluten; the fuel in the starch, the oil and the sugar. In proportion to the cold to which the animal is exposed, is the consumption of oxygen and of fuel; and as the same is true of exercise, it follows that men and animals who are compelled to labor must be better fed, and that even with an ample allowance of food, if their labor is severe, they do not grow fat.—The starch, sugar and other elements which would be converted into fat, are entirely consumed by the process of respiration. If, with the same allowance of food, these individuals are permitted to take less exercise, the fuel is but partially consumed; and a deposite of fatty matter is the consequence. This is shown constantly in the hog and in the whale, animals which eat largely in proportion to the oxygen consumed—in other words, to the exercise they take—and which consequently grow exceedingly fat. It is seen in the bear also, and in the opossum, in which the fat would seem to perform the double office of protecting them against the external cold, and of supplying the internal heat necessary to maintain life during the frosts of winter. And the opposite phenomena are observed in the deer, and animals that like it are active in their habits, the flesh of which is always compara-

tively lean. The oxygen they consume is sufficient to convert into carbonic acid all the carbon of their food, the excess of which would go to the production of fat. To agriculturists these facts have long been familiar, and it is the well known practice with them to confine cattle to small comfortable stalls, and hogs in narrow pens, where the object is to fatten them in the shortest time and with the least expense of food. But we have not space to pursue the subject further at present.—*Louisville Journal.*

EXTRACT FROM A REPORT ON HORTICULTURE,

Read before the Newbury Agricultural Society, at its Anniversary Meeting, July 27, 1842, by MATTHEW HALL.

Peppers should be sown in the first of April, in drills. When properly up, thin to stand about 10 or 12 inches apart, leaving one or two stalks in a place.

Mustard, for winter use, may be sowed in the latter part of August, or first of September, in drills about 18 inches apart, covered very lightly. The bed on which it is sown, should previously be made very rich. As soon as it is up, thin it out so as to let every plant have three or four inches space between them. For spring use, it may be sown in the same manner in January or February. It should be hoed and kept clean.

Beets should be sown in February or the first of March, in a rich, sandy soil, in rows or drills, 18 inches apart. The seed may be planted in the drills, 10 or 12 inches apart, and three or four in a place; after the plants are well up, thin them to one stalk or plant, and attend well with plough and hoe. After they have arrived to perfection in the fall, they may be baked like potatoes, and preserved all winter. Transplanting of beets does not answer well.

Bush or bunch beans may be planted in the last of March, in a rich, sandy soil, in some part of the garden that will shelter them from the north wind, and give them the sun in the early part of the day. If it should be likely to frost, cover them at night. They may also be planted about the full moon in April, and for a succession of crops on to the 4th of July, or even later. They may be drilled in rows two feet apart, and after they are well up, thin to two stalks, 18 or 20 inches apart. Stick (or pole) beans may be planted from the middle of April to July in the same manner as the others, except that they should have more distance, say two feet one way and 3½ the other. Have your land well manured, and attend well with plough and hoe. As good seed is of the greatest importance, the stalks you allow to save your seed from, should never a bean be plucked from, till they are perfectly ripe; then gather, shell them out, and dry them properly in the sun, then put them up in a small bag with some tobacco or snuff, and hang them where they can have the air: the tobacco preserves them from the bug in a great measure. The seed should always be saved from the first beans you plant.

Cucumbers, water melons and musk melons, although they can be raised in a garden, should never be planted there. The reason is obvious—if a garden is not rich land, it should be made rich; this sends up grass and weeds very fast, and vines, after they get properly to running, should never be interrupted, and it would be impossible to keep them free from grass in a garden without moving them; therefore, select the poorest sandy old field you have, fence in your patch, lay it off with a plough twelve or fifteen feet square, in December; dig a hole in every cross, two feet deep and two feet wide, (or wider,) fill it up as soon as convenient with corn cobs about two-thirds full, and beat them down with a maul or crowbar. Let your holes stand open all winter. In the first of March, fill up the remainder of the hole with manure, (that from a hog-pen is best.) Plant from the 1st to the 20th of April; put eight or ten seed in a hill, some of them ten or twelve inches apart. But before you plant your seed, mix some of the earth or sand with your manure on the top of the hill, raise your hill about three or four inches above the level of the earth, for fear of rain settling it below the surface, and drowning your seed or plants—When they are up and have four or five leaves, thin them to two stalks, letting the farthest apart thrifty plants stand. When they commence running, lay them so as to run in different directions, so that one vine will not interfere with another. By the time they begin to run, they should be laid by, having your ground perfectly clean. Generally two ploughings and two hoeings will do them. After they have run three or four feet, they should be confined to the ground with cross sticks, to keep the wind from turning them over, (I mean the watermelon vine.) No sickly or deformed melon should be allowed to set on a vine. If you wish to raise large water melons, let but one mellon set on a vine till it nearly gets its growth; also top your vine. As seed is of the greatest importance, save your seed from those melons or cucumbers, which grow nearest the root of your vine; these are decidedly the best. Vines from these sced wil yield moreand come earlier.

Dr. LEWIS FEUCHTWANGER, of New York, in a letter to the editor of the American Agriculturist, says—The following preparation will effectually exterminate all caterpillars, snails, bugs, beetles, earth fleas, leaf lice, ants and other insects on fields, trees, bushes and hedges.

Take diluted Pyroligneous acid, 1 gallon; white oak bark, 1 lb.; urine, half gallon; garlic, half pound. After soaking the oak bark and garlic for two days in the acid and urine, strain them off and sprinkle once a week or oftener, the trees infected with insects, or the pea, cabbage, &c., and they will be preserved for the season.

Extract from a very sensible Address of JA'S RANKINE, *of Cananadaigua.*

SOURCES OF HAPPINESS.—Surely pecuniary gain should not be considered as the scale in which all things are to be weighed. It has been said that wisdom is better than riches—and it is indeed so. The advancement of fortune is a laudable object; but we have received the capacity for social and intellectual enjoyments, and it could not be meant by the Giver that we should receive it in vain. All our struggles in life are directed to increase our happiness—if, however, we confine our endeavors merely to the enlargement of our possessions, the gratification which may arise from success will still be a gratification to which a rational and reflecting being should be loath to confine himself.—The highest order of happiness, and that least exposed to vicissitudes, is to be found in the cultivation of our intellect, and the improvement of our dispositions. Knowledge may put nothing immediately into the purse; but it will bestow a purer and more lasting enjoyment than any thing contained in the purse can afford. The more we mingle in friendly intercourse with our species, the more will our benevolent feelings be expanded; and if, in addition to mental culture, a man be at the same time in peace with himself, and of charity towards all men be affirmed to have the means of happiness independent of worldly circumstances.

THE FARMER'S LIFE.—Gentlemen, allow me to congratulate you on the happy situation in life, in which those are placed, who are engaged in the cultivation of the earth. In independence, in healthfulness, in amenity, it excels every other. Prudence and economy, and a just estimate of his position in society, are requisite for a man in all situations; but to whom are the facilities to independence so great as to the farmer? Favorably situated for avoiding temptations to be led away by the vanities of society, he is surrounded with every thing necessary to comfortable existence. His life, indeed, is a laborious one; but labor is no evil—it conduces to the vigor of the body and of the mind, and certainly, it is not in idleness that happiness is eve found. The very place in which his labors are carried on is favorable to him. He lives, n o pent up in walls, and in a confined or insalubrious atmosphere, but in the free airs of heaven, with the boundless sky for a roof, and surrounded by every thing that is lovely in nature, and calculated to lead the mind from nature to nature's God. The sentiment of love and admiration of the beautiful works of the Creator, leads us to see him, and to know him, and to adore him. He who can plod on in his fields, insensible to these beauties, is truly of a cloddish heart. He is incapable of experiencing that sublime love of the Deity, which alone can elevate the soul above the miseries that envelope all worldly concerns, and give him as it were, a foretaste of the pure and exalted joys of a future state."

REARING OF CHICKENS.

TO THE EDITOR OF THE FARMERS' REGISTER.—You some time since requested to know my mode of raising chickens, and I take great pleasure in forwarding the same to you.

I must, in the first place, give you my plan for constructing a "hen house," as I consider it one of the most important things about the rearing. My "hen houses" are built of pine logs, with the bark taken off, and chinked in with wood. On the inside of the house, and about one foot from the walls, I plant forks, across which I lay poles for the fowls to roost on, being careful that no part of the poles or forks shall touch the house. About once in four weeks, I have these poles washed or replaced with new ones; by these means I get rid of lice, if any should have found their way to the roost of the fowls. My boxes for the hens to lay in are put upon forks in the same manner, being entirely detached from the house, and are taken out once in three or four weeks, and new nests made for the hens.

Since I have been pursuing this plan, I have never been troubled with lice, nor have I ever lost any considerable number with the gapes, a disease which I am convinced proceeds from the young chickens inhaling hen lice from the parent hen.

In chickens having the gapes, a worm is found in the larynx, near the lungs, which continues to increase in size until the whole aperture in the windpipe is filled up; and the chicken then suffocates. I am convinced that this is the cause of the disease; for if the parent hen is kept clear of lice, the young escape the gapes.

When I find my hens are ready to go to setting, I always, in the early part of the season, set two on the same day, and when they hatch, put them together in coops, or hovers, and feed them on corn bread; until the chickens begin to feather, when I give them small hominy. At this time I take away one hen, and confine her for a few days, when she will become weaned, and again be ready for setting in a few weeks.

In the summer, when the young chickens do not require the protection of the mother to hover them, I frequently give as many as fifty or sixty chickens to one hen.

Last season I set six turkeys, and they only brought out a sufficient number for three of them to attend to. I set the remaining three on hens' eggs, taking care to set a hen at the same time. During the season, each turkey brought out three broods, amounting in all to 150 chickens.

The turkey hens while setting require to be well fed and watered, and if well attended to, will set most of the summer.

Since I have adopted the above rules, I have been very successful in raising chickens, and can recommend them to the patrons of the Register. Very respectfully,

WM. B. GREEN.

CANDLES.—Prepare your wicks about half the usual size, wet with spirits of turpentine, put them in the sun until dry, then mould or dip your candles.

Candles thus made last longer, and give much clearer light. In fact they are nearly or quite equal to sperm in clearness of light.

WEDNESDAY, APRIL 5, 1843.

OPINIONS OF THE PRESS, &c.

We beg leave to avail ourself of this occasion to tender to our brethren of the Newspaper press, and also to those friends who have taken an interest in extending our circulation, our most sincere acknowledgments for the numerous very flattering notices they have taken of the "Southern Cultivator," and their exertions to have it generally disseminated among the planters. It is alone by a very general circulation, that we can hope to accomplish much, in exciting among agriculturalists a spirit of rivalry and improvement, from which we feel confident much good to every class of society will certainly result. We therefore earnestly hope that our friends will not flag in their exertions, and we pledge ourself, that whatever of zeal and ability we can bring to the work of rearing upon a firm basis an Agricultural journal at the South, worthy of the cause in which it is engaged, shall be most cheerfully brought to bear. To accomplish successfully such a work, much depends upon the planters themselves, and we hope they will not consider us importunate in again urging upon them, in this connexion, the importance of giving us their aid, by forwarding to us their views on all subjects coming within the sphere of our work.—And particularly do we desire to have such agricultural facts as are at the command of every intelligent, reflecting planter. We are aware that very few, if any, of our planters are in the habit of committing their thoughts to writing, and many, consequently, feel some delicacy in doing so—but they should not be deterred from it by any delicacy of feeling. All we want is a plain statement, the plainer the better, drawn up in the very language in which they would communicate a fact to their neighbor, and if it should need any polish, we will take great pleasure in bestowing whatever labor we may deem necessary. They should reflect, and we hope they will, that they are a common brotherhood, engaged in the promotion of the greatest work that engages the attention of mankind, and regard it their duty to afford to others the benefits of their experience and observation. If this be done the interest of the "*Cultivator*" will be greatly increased, and its capacity to do good much improved.

To Eradicate Corns.—Take a small piece of flannel which has not been washed, wrap or sew it around the corn and toe. One thickness will be sufficient. Wet the flannel where the corn is, night and morning, with fine sweet oil. Renew the flannel weekly, and, at the same time, pare the corn, which will soon disappear.—*Leeds Intelligencer.*

A FINE BERKSHIRE PIG.

We had, yesterday, the pleasure of examining one of the finest Berkshire male pigs we have ever seen. He has been imported from Ohio, by our enterprising fellow citizen, Col. John Bonner, of White Plains, Green county, and for beauty of symmetry, high form and fine size, is unsurpassed by any pig we have had the pleasure of viewing. He is the produce of Mr. A. B. Allen's of Buffalo, New York, celebrated imported boar, Windsor Castle, out of one of his finest imported sows, and is now about ten months old. Although his appearance at this time has doubtless been materially effected by his long voyage, (having been shipped in the early part of November last, on board a boat that was locked up in the ice on the canal,) he has attained a fine size, and looks to be in fine health, and, we think, will be an important addition to Mr. Bonner's already fine stock. We cannot commend in too flattering terms, the spirit and enterprise with which Col. Bonner has entered into the work of improving the breed of hogs in Georgia, and we sincerely hope we are destined, ere long, to witness a similar spirit of improvement in every department of agriculture.

PLOWING MATCH.

One of the most important steps toward the improvement of agriculture, is the introduction and use of proper implements of husbandry, and the agriculturists of Europe and America, where much attention has been paid to this subject, have instituted the most thorough and satisfactory tests to ascertain the comparative value of every implement in use. With the view of ascertaining the value of the various kinds of plows introduced from time to time, they have instituted at all agricultural fairs "*plowing matches,*" at which the various plows are made to exhibit their capacities for their respective uses, in the presence of a committee competent to decide upon their merits; taking every thing, the width and depth of furrow, the beauty with which each executes its particular purpose, the weight of draft, &c. &c., into consideration.—The committee after minutely scaning every thing, proceed to award the premium to the best plow, and hence it is recommended to the favorable consideration of the public. Although scenes of this sort are very common wherever much attention has been paid to improving the system of Agriculture, they are very rare in the South, and the announcement, a few days since in the city papers, that one would take place on the Commons, drew quite a crowd of persons to witness the novel exhibition, which was got up by the agent, for the introduction at the South, of Barnaby & Mooer's "*Side Hill Plow,*" as it is generally denominated, to show its superiority over all other plows in use at the South for effectually turning land. This plow is constructed with a mould board on each side, and by changing the beam from one side to the other, is made to turn its furrow either to the left or right, or, without changing the beam from the centre, to turn only on one side. We regret much that we have no *cut* that we might exhibit its form to the reader, which would be much more satisfactory than any description we can give of it. They are for sale in this city, and as they surpass any plow we have ever seen used for turning land, we hope our planters will test their capacity and adaption to southern culture. They are highly appreciated at the North and East, and have received several premiums at the various agricultural fairs. Of them Mr. E. Cornwell, in a letter to the editor of the "*American Agriculturist,*" says:—"I am satisfied from a practical acquaintance with the best plows in use, that no plow has yet been invented that can compete with this for any length of time, as a plow for general use. Its ease of draught and its adaptation to every kind and shape of plowing, and the perfect manner in which it performs its work, are advantages that cannot be combined in any other plow."

For the Southern Cultivator.

Lexington, March 18, 1843.

Mr. Jones—Hoping your "Southern Cultivator" may long be the source of valuable information in agriculture, I seize an early occasion to communicate with your readers on the culture of Sweet Potatoes. I am sure I will have the blessing of many a negro, baby and housewife next fall for this letter.

Sir, the old method of planting sweet potatoes in hills and ridges, in this dry climate, and on our hard upper country clay lands, is all wrong. Potatoes must have *moisture* and *soft earth* to do well. But they lack both in the common culture. Hills and ridges are the driest forms in which you can put the soil. *Flat* culture is the only right kind for potatoes, or any thing else, in our burning climate and on our clay uplands. Potatoes should be planted as *flat*, and may, in that way, be planted as *easily*, as corn.

First, break up the land well; then lay off rows four feet wide with a shovel plough; run *deep* in the same track with a rooter; and then, if you want it perfect, deeper still in the same furrow with a common new-ground coulter.—Next, list upon both sides of this in the same way; that is, with shovel, rooter and coulter, one right in the track of the other. This makes deep work, and the deeper the better. It is soon done. Your ground is now ready—deep, loose and moist, and will keep so all summer.

Now for planting and culture. With a rooter draw a shallow furrow on the top of the list, just over the first shovel track, to guide you in dropping. In this drop the seed, cut roots, sprouts or vine-cuttings, twelve or fifteen inches apart, and cover lightly. Plough them a few times, just like corn, running close to the potatoes with a rooter, and finish off each working with a cultivator, or some other plough to keep the middles flat.

This mode of culture is not one fourth as troublesome as hills; the crop is wonderful.—This is not theory, but is my constant practice. By this mode the vines never turn yellow; the crop comes forward early in August, and the owner has no chance to talk about "small potatoes."

Before your Cultivator appeared, I had promised this article to our mutual friend, Clayton, for the agricultural column of his Athens Whig;

but as he will be sure to see it in your paper, he will excuse me for sending it first to your Southern Cultivator; as the proper depository or magazine of all such useful facts in our Georgia agriculture. Yours, &c.

W. McKINLEY.

P. S. Don't fear to try this plan in the approaching planting. There is no mistake in it. It saves time and work, and makes two bushels for one in the old way.

POLL EVIL.—This disease, says the Southern Planter, has generally been considered incurable, but Mr. Samuel Terrill, of Caroline, an old gentleman of the highest respectability, called at our office a few days since, to say, that he had found an unfailing remedy in the little evergreen, commonly called the *ground ivy*. The leaf is gathered and dried before the fire until it can be pounded, when a table spoonful is mixed with an equal quantity of slacked lime, and the swelling, having been laid open to the bone, the mixture is laid in the wound, and kept in place by a bandage. Mr. Terrill says that he has used it himself, and that he has known it frequently used by others, and that, in no instance, has the first application failed to effect a cure.

LIME IN AGRICULTURE.

Of the mineral substances that have been employed to improve the soil, lime is the most important. All our lands seem to me to be susceptible of great benefit from it; and I believe that in many parts of this district it can be obtained on such terms as to create a probability that it may be profitably applied. The theory of its modes of action involves chemical principles, which it would be beyond my limits to attempt to explain here; I may briefly state, however, the facts connected with its various effects.

It renders stiff and tenacious soils more friable—and light and sandy soils more retentive of moisture. It disposes all vegetable matter in the soil to decompose, so as to supply the nourishment of living plants, and it makes the nutritive matter itself more salubrious. These last effects may be seen in familiar instances.—If a little quick lime be added to a heap of leaves or rotten wood, it is soon reduced to black mould; and if a little be sprinkled on the rank spots which get up in pasture fields, and are rejected by cattle, they will shortly be eaten down. It is not more active in rendering the vegetable matter of the soil available, than it is in giving vigor to the plants, and goodness of quality to the grain; and on no grain are its effects so remarkable as on wheat. I knew a gentleman who from having a great command of manure, thought that he might dispense with lime. He raised by measure as many bushels of wheat on the acre as his neighbors; but it was coarser in quality, and therefore lighter, and in the British markets great discrimination of price is made on account of quality; so that he lost in two ways. He had at last recourse to lime, and with complete success.

In cold and humid climates, it is not considered that old turfy lands can be profitably broken up without lime; the straw will be abundant, but the grain light and unmatured—treated with lime, these lands are the most productive. In our climate, the vegetable matter has no such a tendency to become peaty and inert, and lime may not, to such a degree, be necessary for the purpose of promoting decomposition; but it would in every case make our wheat of better quality. In our best lands, it would give health and vigor to the straw and render it less obnoxious to the diseases to which luxuriance is exposed, and it would make lands, at present too rich for bearing grain, capable of producing healthy and productive crops. From what has been said, it will follow, that it would be improper to apply lime to impoverished land, unless at the same time accompanied with manure, without which it would aid in the robbery of the soil. For other reasons, it should not be applied to wet land.

In calculating the expense of liming, the permanency of its effects should be taken into account. If a proper dose be administered, there will be no need of a repetition of it for 15 or 20 years. What the dose should be, must depend on the quality of the land; but generally speaking, it should be increased as the land is more adhesive, or as it is more filled with vegetable matter. There are no soils, probably, that would be benefitted by less than 100 bushels to the acre, or which would require more than 300 to produce the maximum effect. As, in proportion to the mass of the soil, the quantity of lime used is small, the two should be mixed together as equally and intimately as possible. The lime may be allowed to lie till it falls down into a state of flour, and then be spread out, when the soil has been previously well pulverized.

Rankine's Address.

HOME IMPROVEMENTS—GOOD ADVICE.

To the editors of the Tennesree State Agriculturist:

GENTLEMEN:—Is it not the desire of every parent that their children should love home? If so, beautify and adorn your homes, so as to make them the most pleasant and loveable place to them.

"The spring time is coming," the season when dame nature decks herself in her gayest attire, and all things living seems endued with new life and vigor. Begin then with nature; she will lend you kind assistance; plant trees, fruits and flowers, tend, work and water them, let your children assist you, give each his portion in the labor of love—who that ever planted a flower, and watched it from the putting the unsightly root into mother earth, to the first peeping forth of the green leaf, to the full expansion of its beautiful bloom, but looks back with pleasure on his sensations of delight and exultation, as he culled it for the one he loved best? how his face glowed and his heart beat as he eagerly displayed the prize! Who can walk in the garden at dewy eve or rosy morn, inhaling the delightful perfume rising as incense to the giver of all good, from every bud and flower for the sparkling drops kindly sent to refresh and invigorate, and not feel his own heart lifted up in praise and adoration for so many blessings?—The mind is naturally led to harmonious reflections by contemplating nature in her most alluring forms. Adorn your homes then with all her choice productions, so that in after life, when your children are surrounded with care and trouble, home will rise up as a green spot in memory's waste. Let your children share your pursuits, it will make them love home better, more affectionate toward each other, and give them more confidence in you; they will find there is indeed "no place like home," instead of an irksomeness and reserve in your presence, they will feel confidence and consider you their best friends and companions.

Are not the Swiss and Scotch more attached to their wild, rugged, and often barren country, more than any other people? It is because they bestow more labor on it, they toil incessantly in tilling the earth, and feel more affection for that spot. In most countries, the great struggle is, to keep the homestead from generation to generation, while we still continue the "squatting" propensities of our forefathers; our children, like a flock of birds, leave us as soon as fledged—not but I would have them independent, have them so by all means, and to have them so, I would do away the great love of speculation, the making haste to be rich, the effects of which so many are sinking under at this very time; and make our boys *quiet*, *sober* and *intelligent* men, our girls *well informed*, cheerful, healthy, amiable and affectionate. If you wish your boy to be a good son, good brother, good husband and good man, make him love home, it will also deliver him from the manifold temptations that beset a young man's path—he will, by sharing his mother's and sister's pursuits, acquire a greater interest in them, and have a more affectionate regard and greater sympathy with them; it will rub off the rough points of his character, refine and polish him, strengthen and exalt the mind of the sister, add ease and grace to their deportment with the rougher sex. By making home agreeable, you heighthen the affection of your children for yourselves, and prevent their seeking enjoyment and amusement elsewhere—you will have them more under your parental eye, and thus be able to check many an embryo fault kindly and gently, which, if left unrestrained, would wring many a tear of anguish frow your hearts. Has not the Father of ALL made his universal garden beautiful and lovely in the extreme? Is it not enriched with all that is pleasant to the eye and grateful to the taste; even every thing that the heart of man can desire, to make this, our temporary home, a paradise; and shall we not follow such a glorious example, and make the transient home of our children pleasant and sweet. By adorning, making them pleasant within and without, they can in truth say, "there is no place like HOME."

If you think, dear sir, that your paper will not be disparaged, you shall again hear from

AUNT CHARITY.

MESSRS. EDITORS—I send you the above as a very useful and convenient table that I have compiled for the "Planter." The calculations are, I believe, entirely correct.

Yours, respectfully,

PH. B. WHITE.

Southern Planter.

LICE ON CATTLE.—1. Mercurial ointment rubbed on the animal from the crown of the head to the root of the tail, down the back bone, will effectually kill lice in a day or two. This, however, is a dangerous remedy to use, unless the animal is kept in the stable, and requires great care to preserve him from the effects of cold and wet.

2. Corrosive sublimate is another effectual remedy. This is to be applied as before prescribed, but, like No. 1, is dangerous.

3. A strong decoction of larkspur is also a sure and safe remedy. This should be applied as recommended for No. 1.

4. Spirits of turpentine is also a sure remedy. It should be applied as No. 1.

5. A decoction of tobacco, applied as No. 1, will destroy the lice.

6. A mixture of Scotch snuff and fish oil, rubbed on the affected parts, will destroy the lice.

7. A mixture of soft soap and Scotch snuff, well rubbed on the parts, will also eradicate them.

As an auxiliary to whatever remedy may be used, the currycomb and brush should be freely applied, after a day or two, in order that the hide and hair of the animal may be kept clean. No animal which is well fed, and daily curried and brushed, will either breed or retain lice; the latter operation, however, few who have much stock can regularly attend to.—*Am. Framer.*

TOMATOES FOR COWS.—It is not generally known (says the P. C. Advocate) that this vegetable is a superior article of food for milch cows. We have tried it two summers, and it is decidedly superior to any other vegetable we have yet tried. They add greatly to the quantity as well as to the richness of the milk, and give a rich golden color to the cream and butter, which is at least pleasant to the eye, even if the flavor is not so improved. We do not know, however, that they impart any richer flavor to the butter.

We have known a cow to refuse them when first offered, but soon became very fond of them; others, we believe a large majority, eat them greedily from the first. Thus far we have fed them only in the raw state; but if boiled with corn meal, say half and half, or two-thirds tomatoes, they will doubtless be far better.

To one who has a dairy farm, the cultivation of an acre or two in tomatoes would be repaid by greater profit than any vegetable we know. From one acre not less than eight bushels may be gathered daily from July until frost. There is some trouble in picking them, but then nearly every farmer has children; his little boys—ay, and his big ones too—would not be the worse for a little work. We should be glad to see the experiment tried on a larger scale than ours, and to learn the result.

SPAYING.—We have received from L. Bishop' Esq., of Smyth county, Virginia, the following account of the process adopted in spaying pigs by Rufus Rouse in that neighborhood:

"Fix a plank three feet high. Lay the pig upon the right side on the plank, with two persons to hold the fore and hind legs and mouth. The implements used are a sharp pocket knife and a long crooked needle, with cutting awl-blade edges, and a strong waxed thread. The operator takes his knife and shaves off some of the hair, three and a quarter inches from the hip-bone; he then makes an incision crosswise, so that he can introduce one finger to bring out the uterus; he then cuts off the whole of the uterus and throws it away; he then enters the needle on one side of the wound and brings it up through the other, and secures it with a strong knot. One stich is sufficient. A mixture of tar and hog's lard is used to smear the wound.—This mode of operating is the invention of Capt. Rouse, and I am in favor of the plan; considering it more safe and less troublesome than the other methods."—*Cultivator.*

TO IMPROVE A PINY OLD FIELD.—First belt the trees and cut down the bushes. The following year cut and burn every thing into coal which is large enough, and scatter the burnings. That which is not large enough for coal should be spread on gullies and galls; and this should be completed by the middle of March. Now mark off the ground with a coulter, sow oats (and grass seeds, if you please,) and cover with the same implement. For the purpose of making equal distribution of the manure, and to avoid cost in carriage, the kilns should be placed at about fifty feet distant; and that they may be of about equal size wood should be moved as required. Or if there be a surplus, the wood or coal can be moved elsewhere. At fifty feet distant, we have about eighteen kilns to the acre, which, if producing only one hundred bushels of burned earth and coal to the kiln, is one thousand eight hundred to the acre, which I would apply to the spot, and then comes the blessing.

OLD FLU.
Southern Planter.

CEMENT FOR GRAFTING.—Two pounds and two ounces of rosin, six ounces of tallow, and ten ounces of beeswax. Melt them together, and turn the mixture into cold water, and let it remain till cool enough to handle; then work it as shoemaker's wax. We have used cement thus made, and found that it remained on the stock for years. It is not so soft as to run in hot weather, nor so hard as to crack in cold weather. All of the ingredients for making this cement must be of a good quality.

MECHANICS.

"Out of nothing nothing comes."

The laws of nature, unlike human laws, can neither be changed nor evaded; and for a want of a proper knowledge of simple and unchangeable laws many men waste time and money in trying to produce great effects by insufficient means.

The mechanical powers, as they are called, do not, and never can, create power; they only modify its application.

The power most easily measured is that of gravity or weight; and it is the cheapest of all powers or first movers, when, as in the case of a water fall, nature constantly winds up the weight for us for nothing.

Suppose, then, we have one thousand pounds of water falling ten feet in a minute. No human contrivance can make that water raise more than its own weight to the height of ten feet in the same time. It cannot raise quite as much, for the friction of the machinery must waste part of the power; but, as it may be a small part, let us omit the friction from these calculations.

The effect of the mechanical powers is to enable us, while the original power remains the same, and the rate of its motion the same, to exert a greater power with a slow motion, or a lesser power with a quicker motion. But, in all such cases, the power produced, multiplied by the speed with which it moves, will be found to give the same product.

Thus, one thousand pounds falling ten feet in a minute, may be made to raise ten thousand pounds one foot in a minute, or one hundred pounds one hundred feet in a minute, the same power being required in each case; but no man can make it do more, for, if he did, he would create nothing out of something, which is contrary to a law of nature.

For this reason, all attempts to make a mechanical perpetual motion, have failed, and forever must fail, as such a machine would be equivalent to making a weight raise another equal to itself to the same height in the same time, and enough more to overcome the unavoidable friction of the machine, which friction, however small, is sooner or later to stop the motion, unless an additional power is applied sufficient to overcome the friction.

Therefore every man, who is trying to make a perpetual motion or any other machine which he expects to do more than the power applied to work it, is wasting his time and money in that which will be certain to end in disappointment.

Farmer's Companion.

TO HOUSEWIVES.—Recent experiments in more than one family in this city, says the Delaware Gazette, have established that the plant known to botanists as the *Pologonum punctatum*, commonly called water pepper, or smart weed, and which may be found in great abundance along ditches, roads, lanes and barn yards, is an effectual and certain destroyer of bed-bugs. It is said to exercise the same poisonous effect on the flea. A strong decoction is made of the herb, and the places infested with the insect are carefully washed therewith. The plant may also, with much advantage, be strewn about the room. Elderberry leaves, laid upon the shelves of a cupboard, will also drive away roaches and ants in a very short time.

RED OR BLACK ANTS.—Take a few sprigs of green wormwood, and place them in immediate contact with red or black ants, and they will disappear. I have found this to be effectual after using every other remedy within my limited knowledge.

Another remedy is to sprinkle chalk around the places they frequent. It is said the chalk will cause them to make their exit, but I have not had occasion to prove it.—*N. E. Farmer.*

SOAK YOUR SEED CORN IN SALTPETRE.—It destroys the worm, is not relished by crows or squirrels, and yields much more abundantly than when planted without.

PEACH TREES.—When bearing trees are planted in low places, the blossom buds are urged forward by the warmth of day, and the increased severity of night frosts destroys them. But on hills, these extremes of heat and cold do not occur; hence they generally escape. One of the early settlers of Wayne county, near Palmyra, twenty-four years ago planted a peach orchard on a hill nearly one hundred feet above the average height of land; and during twenty years since they first began to bear, he has lost only one crop by frost.—*Cultivator.*

MODE OF INCREASING THE POTATOE CROP.—An English writer says, by carefully removing the buds as they appear on the potatoe vines, the crop of large ones is very much augmented. The theory is plausible, and worthy a fair trial.

AUGUSTA MARKET.

TUESDAY P. M., April 4.

Cotton—Since our report of last Tuesday, our market has assumed a little more activity, but as holders seem unwilling to accede to the demands of dealers for lower rates, a large business has not been done. We quote 3¾ to 6 cents as extremes of the market, though the major part of the sales are made at 4½ to 5¼ cents.

Business.—During the entire month of March, the weather was extremely unfavorable for business operations, which combined with the low price of cotton, have materially effected the spring trade, and our dealers complain that although their stocks are very fine the trade is very limited.

Exchange continues at par on Savannah, Charleston and all the Northern cities. Central Bank bills are sold at 28 ℔ cent discount. Alabama notes 20 @ 25 ℔ cent discount. State 6 per cent Bonds are in demand at 50 cents.—There are no transactions in the bills of other depreciated banks, as there is no confidence in any of them.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., APRIL 12, 1843. No. 6.

SUGAR FROM CORN.

We have received a great number of inquiries from different parts of our country, on the subject of manufacturing sugar from Indian corn, of which the following will embrace all the essential points, and to which we shall give as full a reply as the present condition of the manufacture will admit.

1. What is the best method of growing corn intended for making sugar?
2. Time of gathering and preparation for grinding?
3. Machinery for the manufacture?
4. Process of boiling, and granulation of the Sugar?

1. In planting corn for sugar, two objects must ue kept in view—the securing the greatest growth of stalks, and the prevention of the formation of ears. The kind of soil required for a great growth of corn, is so well known that it is unnecessary to describe it here. It must be rich, and should be friable, that it may be cultivated easily. A heavy clover lay, manured, and then turned over, rolled and the surface harrowed fine, makes a good soil for a corn crop. Mr. Webb, the most successful manufacturer of sugar thus far, directs that the corn be drilled in rows north and south, that the influence of the sun may be felt as much as possible, the rows to be two and a half feet apart, and the plants in the rows not more than two or three incher apart. This thick planting on a rich soil gives a great stand of corn, and in considerable degree prevents the formation of ears, as ears cannot be expected where the corn is as thick as is here directed. Mr. Blake of Indianapolis, made an extensive experiment last year, and from 4½ acres produced about 280 gallons of excellent molasses. He planted his corn, or rather drilled it in rows four feet apart, plants close set in the rows, but distance not stated.—It is probable in planting corn for sugar, something should depend on the variety selected; as it is evident the small northern kinds would requre closer planting than the tall southern or western kinds. We have not learned that any experiments have been instituted to test the comparative value of the several varieties of corn for sugar; though it is certain that large stalks yield more juice than small ones, in proportion to their size.

2. Theory indicated that a large portion of the sugar in the cornstalk would be lost, if ears were allowed to form; and experiments demonstrated that such was the case. When corn is planted thick no ears will form, or only small and imperfect ones. If ears form, they must be broken or cut off; not too early, as their tenderness greatly increases the labor required. Any time previous to the formation of the grain on the cob will be soon enough. When the stalk is fully matured, or ripe, the process of cutting off the tops or the blossom part, and stripping off the leaves, must be performed. The early northern kinds will be fit for stripping in August, the later kinds will continue to ripen until in September or October, or until killed by the frosts. The tops and blades must be secured for fodder, of which they make the best quality. When topped and stripped, the stalks are cut up by the bottom, close to the ground, bound in bundles, and taken to the mill for grinding. It is found by experience that the corn can be topped and stripped much more rapidly on the hill, than if cut up previous to those operations. If the tops and leaves are not taken off, a quantity of the juice will be lost, and the formation of sugar rendered more difficult.

3. The machinery required for the manufacture of cornstalk sugar is the same in effect as that used in making cane sugar. It was at first supposed that wood cylinders might be used for the corn stalk, instead of the iron ones requisite for the cane, and all the experiments hitherto made, have been in mills of this kind. Experience shows, however, that iron mills must be used, it requiring more hardness and firmness than wood possesses to operate successfully for any length of time. We give the figures of two mills for grinding corn or cane, one upright, and the other horizontal. The first (fig. 29,) is a figure of the mill used by Mr. Webb and others, the past season, and is of wood, worked by horses. The other mill is of iron, and may be worked by water, steam or horse power. Mr. Webb describes the first mill as follows: "It may be made with three upright wooden rollers, from 20 to 40 inches in length, turned so as to run true, and fitted into a strong frame work, consisting of two horizontal pieces, sustained by uprights. These pieces are morticed to admit wedges on each side of the pivots of the two outside rollers, by which their distances from the middle one may be regulated. The power is applied to the middle roller, and the others are moved from it by means of cogs. In grinding, the stalks pass through on the right side of the middle cylinder, and come in contact with a piece of wood work called the dumb returner, which directs them backwards, so that they pass through the rollers again on the left side of the middle one." The arms and braces used when the mill is worked by cattle or horses, are seen in the engraving. The iron mill does not differ greatly in principle from the wood one, except that the distance of the side rollers from the centre one is regulated by screws, as seen in the engraving, and that when propelled by animal power, the upper roller is turned by cogs at one end, moved by others on a vertical shaft. The iron mills are the most expensive in the outset, but they are the most durable, less liable to get out of order, and separate the juice from the stalk much more perfectly than the wood mill.—The experiments of Mr. Webb, the past season, from which so much was justly anticipated, failed in a great measure in consequence of his mill giving way on the second day of its use. Mr. Blake, whose well conducted experiment we have before noticed, used a wood mill, and found that a large part of the juice was lost, by the surface of the rollers soon becoming uneven, and not pressing the stalk properly. It is probable, therefore, that iron mills will be found the most economical in the end, and there is no necessity for their being very expensive. In both cases the rollers must move in or over reservoirs for the receiving the juice as it flows from the corn stalk.

4. We have not known, or heard of a single instance, where the attempt to manufacture sugar, or rather syrup from the juice, has failed.—The valuable report of Mr. Ellsworth, contains statements from all parts of the country, of the success which has attended the conversion of juice into syrup, but the instances were comparatively few in which the granulation of the syrup, or its conversion into sugar, was effected. In this, we apprehend, the greatest obstacle to the manufacture will be found. The simple fact, however, that such conversion has been repeatedly effected, shows there is nothing but experience and skill wanted to insure a result at all times. When the manufacture of beet root sugar first commenced in France, granulation of the syrup was almost impossible; now the process is as certain and effectual as in the case of the cane or maple. The great source of the difficulty seems to arise from the rapidity with which the juice passes into a state of partial fermentation, rendering its immediate reduction after extraction, indispensable. Beet root juice ferments immediately after it is pressed out, and it is said that in the West Indies, the purest cane juice will ferment in twenty minutes after it enters the receiver. Mr. Webb kept some corn juice for an hour without injury; but a great variety of experiments prove that it should be boiled as soon as possible. We give from a letter of Mr. Webb's, the following account of his process, because it is the result of practice rather than theory, he having made a beautiful sugar for two years by the process:

"The juice after coming from the mill, stood for a short time to deposit some of its coarser impurities. It was then poured off, and passed through a flannel strainer, to get rid of such matter as could be separated in that way. Lime water, called milk of lime, was then added in the proportion of one or two table spoonfulls to the gallon. It is said by sugar manufacturers, that knowledge on this point can only be acquired by experience; but I have never failed in making sugar from having too much or too little of the lime. A certain portion of this substance is doubtless necessary, and more or less than this will be injurious: but no precise directions can be given about it. The juice was then placed over the fire, and brought nearly to the boiling point, when it was carefully skimmed—taking care to complete this operation before boiling commenced. It was then boiled down rapidly, removing the scum as it rose.—The juice was examined from time to time, and if there was any appearance of feculent particles, which would not rise to the surface, it was again passed through the flannel strainer. In judging when the syrup is sufficiently boiled, a portion was taken between the thumb and finger, and if, when moderately cool, a thread half an inch long could be drawn, it was considered done, and poured into broad shallow vessels to crystalize. In some cases, crystalization commenced in twelve hours, in others not till after several days."

The following is a condensed view of the directions given by Prof. Mapes of New York, a gentleman who has paid much attention to the subject. The stalks (cane or corn) to be cut as ripe as possible, but before any acetic acid is formed; litmus paper will turn red if any acid is presented. Express the juice without loss of time, as every moment after cutting will deteriorate its quality. Clear lime water, one quart to 100 gallons of juice, to be added as soon as expressed, unless the juice shows acid with the litmus paper, when the lime is to be omitted, and a solution of sal. soda, or soda ash, added till it is precisely neutral. In this state, the juice must be evaporated in such an apparatus as to finish its change in 30 minutes. Unless boiled quick, good crystalization is not to be

expected. The time occupied from the cutting to the finishing the boiling, should not exceed one hour. To know when boiled enough, use Farenheit's thermometer; 239° or 240° is the proper point. The instant a charge is finished, it must be thrown into a cooler large enough to contain several charges. The second charge, and so for each one, must be mixed with the preceding, by gently stirring, but no more stirring should be used than is necessary, as it will be injurious. When all is boiled, let the mass cool to 175° and then fill the sugar molds, which should hold not less than 14 galls. There must be a plug at the bottom of the mould to allow the molasses to escape.

One of the most important steps in the process, and which is essential to the formation of sugar, is quick boiling. Long boiling renders the syrup dark, and prevents granulation. Mr. Webb, the last year, found it necessary to discard his former deep boilers, and substitute broad shallow vessels, in which the evaporation would proceed rapidly. The sugar made in this way is of a finer quality than that made by longer boiling, and crystalization is more perfect and certain. Syrup, however, made by quick boiling, as directed by Mr. Mapes, retains more of the peculiar taste of the corn stalk, than when boiled for a longer time. The sugar is free from this flavor, and Mr. Webb, to remove it from the molasses, recommends, after it is drained from the sugar, to dilute it with water, and boil it until this taste is lost. It is very probable, we think, that as the subject is farther investigated, and science is brought more efficiently to the aid of the manufacturer, that the little obstacles impeding his progress will disappear, as they have done in many other cases already.—Where failures in the formation of sugar have occurred, (every attempt to make molasses has succeeded,) they can easily be traced to the imperfections of the machinery, or the inexperience of the manufacturer, and will not be liable to again occur. There is scarcely room for doubt that a vast and profitable manufacture is opening upon the country, particularly the corn regions of the west and south; and there is every indication that the great importation of foreign sugars will soon cease, if not be changed to exportation.—*Albany Cultivator.*

[Accompanying the above article, in the Cultivator, were three engravings, representing—1st. The mill used by Mr. Webb; 2d. Side view of an iron mill; 3d. End view of an iron mill, which we regret we are unable to lay before our readers. —*Ed. South. Cult.*]

Soaking Corn to feed Horses.—One of the best farmers in the vicinity of Baltimore, saves one-third of his corn, by soaking it before he feeds it to his horses. He places two hogsheads in his cellar, secure from the frost, and fills them with ears of corn, and pours on water to cover it. When well soaked, he feeds it to his horses, and when one cask is empty, he fills it again and feeds from the other. By the time one is empty, the corn in the other is well soaked. The cobs are so well soaked that the horses eat the whole, and they require only two-thirds as much corn when prepared in this way, and there is no doubt that this preparation and the eating of the cob with the corn, renders the food more wholesome.—*Farmers' Journal.*

Keene's Marble Cement.—This is a combination of plaster of Paris (Sulphate of Lime) and alum. Common *boiled* plaster is steeped in a saturated solution of alum and then re-calcined and reduced to powder when it is fit for use. Although not capable of standing weather this substance is now attracting much notice from the beautiful stucco which it forms, resembling marble. It may be colored by simply mixing the color with the water used in applying it. The hardness of the substance and its beautiful polish, have brought it into use for interior decoration.

THE ORCHARD.

Notwithstanding we have said much in former numbers in reference to the orchard, still we think it a matter of so much importance to every one, that much more may be said with great propriety. Whether we are farmers, gardeners, lawyers, doctors, merchants, mechanics, or pursue any honest calling whatever, and keep house, we are certain to have a little land about us, which may be the means of giving us delicious fruit, by a little attention. A garden of half an acre, may be made to produce a sufficiency of vegetables for a small family, and quite a variety of fruit trees besides.

The situation best adapted to most kinds of fruit trees that will stand the winters in Tennessee, is a northern exposure. The only advantage in such a situation is, that the sun has less effect, and the north winds greater influence than on a southern exposure; and by this means the buds do not put forth so early and are not so liable to be injured by frosts. Peaches are said to do best on the margin of rivers and near water; but we presume the only advantage is the protection of the water from cold weather.—While on this subject it will not be inappropriate to remark, that old orchardists tell us, if earth or litter to the depth of three or four inches be thrown round fruit trees while the ground is frozen, the buds will be kept back till after danger is all over from cold. We are also told a wet hempen rope thrown over the tree on frosty nights will prevent any harm befalling the fruit. A high hill is not a bad situation for cherries, apples, pears, peaches, nectarines, quinces and apricots; on the most exposed north hill side, or a wall or fence protection from the sun, is the only location suitable for gooseberries, and is the best also for currants.

The soil most suitable, is a sandy loam, neither very rich nor very poor. A shallow substratum of rock or very tenacious clay will not answer.

The best time of transplanting for most trees is the spring. However, if trees were taken up in the fall and buried, or "heeled in," as gardeners would say, till spring, and put out, the management would be good. Every thing does best when it begins to grow immediately after being transplanted. Evergreens will do well only in the spring, or at least this is the writer's experience. There is danger of being loosened by winds, if put out in the fall, and the life of the tree seems to be wasting from the time it is planted till the sap starts, and it is safer to transplant a tree after the leaves start, if carefully managed, than if put out in autumn.

The proper mode of transplanting is, first to have pits dug from one to three feet deep, and not less than three feet in diameter, and if larger it will be better. Let the dirt be thrown out till the pit is the depth intended, then shovel in rich earth till the pit is filled within from eight to twelve inches of the surface in proportion to the length of the roots to be inserted. Then let a careful hand hold the tree. First see that it will be about an inch deeper when the pit is full than it grew. Spread all the roots, if possible, at full length; then let the earth be sprinkled on the roots till they are quite covered; the man holding the tree should shake it at the same time, that the earth may come in contact with all parts of the roots. When the roots have a couple of inches of earth, press with the foot gently all over the pit; then fill it till the ground is a little higher round the tree than it is at a foot or two's distance, that water may not settle at the roots and destroy the tree. The whole should be pressed with the foot. If manure is put in the pits, care should be taken that it is not too fresh and rank. Let it be well rotted, and if it is a compost of stable dung or leaf mould, with one third part of leeched ashes, it will be very good. The true system of manuring, is not to put it in immediate contact with the roots, but place it near the surface, and the tree will get all the benefits and run no risks of injury.

To make sure of getting the trees to live, a stake as high as the trees should be driven by each, and the trees made fast by a string.

The heading of the tree is an operation to which little attention is given by most persons, yet there is scarcely any thing more important to the judicious management of an orchard. By heading a tree, we mean that the branches should come out at a proper distance from the ground, and at regular distances from each other. For the sake of convenience in walking through an orchard, or cultivating it in any way, the branches should not grow on an apple, pear or peach tree, not less than from five to six feet from the ground. In making a head care should be taken that the tree does not fork or prong about equally, for when this is the case it will be apt to split down. There should be a main stem, and the branches should grow regularly one above another all around the main trunk. If young trees grow with a single stem, seven or eight feet before sending out a lateral, as is often to be seen, head it down or cut it off where it is desirable for the head to commence, and the branches will come out at the proper places.

By care, trees may be put in a shape that will give the orchard quite an ornamental appearance, and they will be full more beautiful and vigorous than when suffered to grow as circumstances may direct. It is also a matter of some moment in forming heads to trees, to notice that neither the larger nor smaller branches crowd together. An open head for good health and large, well riped fruit. Before closing these remarks, we must urge upon our readers the necessity and utility of selecting the best fruits of every kind. If those who wish to put out fruit trees, have not such as they want, let them apply to those who have, though the cost may be considerable. Indifferent trees, like noxious weeds, are a pest, but good fruit trees make the most punctual payments for all the land they occupy.—*Tenn. Agriculturist.*

PRUNING FRUIT TREES.

As pruning trees is confined to no particular season, some directions in the present number may be acceptable.

The first thing necessary is a good sharp knife, which is not always at hand.

The second object is to ascertain what part must be cut away, and what should remain.—To be capable of this requires a knowledge of fruit growing, in general, and vegetable physiology and the nature of each kind of tree, in particular. The operator should examine if any of the branches come out too low, and if there are any inclining, or crowding the better proportioned parts of the tree. Such should be taken off. There is said to be more danger in leaving the tree with too much than with too little wood.

With large branches a small saw should be used, and if the operator will use a smoothing plane to leave the wound perfectly free from bruises and rough places made by the saw, the healing may be expected much sooner. In pruning small trees, let one foot be placed near the root, then hold in the left hand firmly the branch to be cut, insert the knife close to the body of the tree, and if possible let the work be done by one smooth cut. The closer to the body of the tree the cut is made the better. Limbs cut at a half inch or inch from the trunk, must rot away, or the tree must become much larger before the healing can be effected, and in the mean time these wounds are most liable to produce serious diseases.

There is much dispute about the proper time of pruning. While some urge the winter or spring the only suitable time, others with as much vehemence, and indeed argument, argue for exclusive summer pruning. From our knowledge of the subject, we have no idea either system is wholly true. Any one who has had a little experience will see, even in the absence of philosophy, that branches cut away in the summer, heal over sooner than if the pruning be done at any other time; and he will also see, there are not a few young shoots which come

out in the summer, which are not needed, and should be cut off before they take the nourishment from the better parts of the tree. On the other hand, there are often awkward and unnecessary branches found on the tree in the winter, and even parts of the tree killed or much injured by the severe cold of winter; and this shows the absolute necessity of spring pruning. To conclude the subject, the writer has no doubt the pruning should commence in the latter part of the winter, or early in the spring, and continue as circumstances suggest through the whole growing season. If either spring or summer pruning be neglected, the trees cannot look so well or do so well.—*Tenn. Agriculturist.*

PRUNING FRUIT TREES.—It will be found upon experiment, that a wound made on a tree in March or April, will look black as soon as the sap begins to flow, and that the sap will ooze out until the leaves have put out so as to receive it; while a wound made in June, will remain white and immediately commence healing.—And a tree that has been broken by being loaded with fruit, or otherwise, while the tree is green with foliage, the wound will look white and the wood remain sound; while one broken in the winter by snow, or from any other cause, will look black and decline to decay.

It has been my humble lot to spend the most of my time in the spring and fore part of the summer in engrafting and pruning fruit trees, and my experience goes to prove that the best time for pruning is when the leaves are full grown, and the tree is vigorous and in a growing state. For at this season the sap has been spent in the foliage, and the pores of the wood are filled, so that when the limb is taken off, the sun and warm weather will dry the end of the limb and close the pores of the wood against the weather, and the sap will keep the limb alive to the very end, and the healing will be perceived immediately.—*Boston Cultivator.*

TO PROTECT FRUIT FROM LATE SPRING FROST.

The following article appeared in the "American Farmer" last spring, and attracted our attention on account of its novelty and ingenuity. Since that period, we have seen a gentleman who assures us he had tried the preventive recommended with the most entire succes. It is at least curious, and for the preservation of the fruit of a particular and favorite tree, might be esteemed useful.—*Southern Planter.*

"Many expedients have been resorted to for the protection of fruit from the blighting influence of late frosts. Throwing a sheet over the tree, hanging iron upon it, kindling a fire under it, &c. have each been found to have a beneficial influence, but none have been more efficient than the experiment which I am about to describe.

"My friend, Major Ruff, who is a virtuoso, lately informed me that many years ago he saw it stated in a French paper that by throwing a hempen rope over the top of a fruit tree, when in bloom or near the time of blooming, and by letting its lower end touch the ground, the tree would thus be protected from the influence of frost. This I thought quite rational and philosophic, I accordingly made the experiment. To prove more fully the *modus operandi*, I took two dishes half filled with water, and set them a few feet distant under the tree, on the night before an expected frost, the tree being nearly in full bloom. Throwing the rope over the top of the tree I let the other end hang in the water of one of the dishes—the event proved the correctness of the theory. There was a hard frost on the morning and the dish into which the rope was deposited, contained ice of the thickness of a dollar, while that in the other dish was scarcely of the thickness of paper.

"The philosophy of the above experiment is this: the rope, which was previously wetted, was a conductor of heat; the air, and of course the limbs of the tree, became *colder* in the night than the earth—the rope conducted the heat from the earth to the tree, thus keeping up an equilibrium and preserving the tree from frost.

"As far as my observation extends, the critical time for fruit is long before it is in blossom: but it is nevertheless true, that severe and protracted cold at that time, or even later, will destroy the fruit. This was the case last year.—The fruit was killed by severe frost after it had been formed.

"There is not in my mind a doubt that by attaching a rope to each tree of choice fruit, and thus letting it permanently remain through the winter and spring, that the fruit would be secured from the effects of frost.

"To the incredulous and the supercilious, who balance their grist all their lives with a big stone—who, sufficiently wise, despise knowledge and instruction, the above may appear unworthy their attention. Let such be informed that it is not less philosophic than lightning rods attached to buildings to protect them from the influence of electricity—let them be informed that

"There are more things in heaven and earth
Than their philosophy has ever dreamed of."

EXTRACT FROM H. COLMAN'S ADDRESS.

Of all the conditions of men, and I have mingled with every variety, I believe in truth that none is so independent as that of an industrious, frugal and sober farmer—none affords more the means of contentment and substantial enjoyment—none, where the education has not been neglected, presents better opportunities for moral and intellectual improvement—none calls more loudly for religious gratitude—none is suited to give a more lively and deeper impression of the goodness of God. Some years since, in the most rugged parts of New Hampshire, among its craggy cliffs and rude and bold mountains, I was travelling on horseback, and came suddenly upon a plain and moss-covered cottage in the very bosom of a valley, where the brave settler had planted himself on a few acres of land which alone seemed capable of cultivation. Every thing about the residence bespoke industry and care. Being fatigued, I stopped to ask refreshments for my horse. A hale young girl of about fifteen, bareheaded and barefooted, but perfectly modest and courteous, with all the ruddiness of Hebe, and all the nimbleness and vigor of Diana, went immediately for an armful of hay and a measure of oats for my horse; and then kindly spread a table with a cloth as white as the snow-drift, and a bowl of pure milk and brown bread for his rider. I never enjoyed a meal more. I offered the family pay for their hospitality, but they steadily refused, saying that I was welcome. I was not willing thus to tax their kindness, and therefore took out a piece of money to give to one of the children that stood near. "No," said the parents, "he must not take it: we have no use for money here." "Heaven be praised," said I, "that I have found a people without avarice. I will not corrupt you;" and giving them a hearty thank-offering, wished them God's blessing, and took my leave. Now here were these humble people, with a home which, if it were burned down to-day, their neighbors would rebuild for them to-morrow—with clothing made from their own flocks by their own hands—with bread enough, and beef, pork, butter, cheese, milk, poultry, eggs, &c., in abundance, a good school for six months in the year, where their children probably learned more, because they knew the value of time, than those who were driven to school every day in the week and every week in the year—with a plain religious meeting on Sunday, where, without ostentation or parade, they met their neighbors to gather the gossip of the neighborhood, to exchange friendly salutations, to hear words of good moral counsel, and to worship God in the most simple but not the less acceptable form—and, above all, here were hearts at peace with the world and with each other, full of hospitality to the passing stranger, uncankered by avarice, and undisturbed by ambition. Where upon earth, in a humble condition or in any condition, shall we look for a more beautiful example of true independence, for a brighter picture of the true philosophy of life?

AGRICULTURAL SCHOOLS.

The subject of directing the education of youth to agricultural pursuits, in order to introduce a more enlightened system of agriculture, is beginning to attract considerable attention in some of the States. In Virginia, particularly, we notice much has been said and written on the subject by some of her most distinguished and intelligent men. Among others, the editor of the Richmond Enquirer has taken the field in defence of such a system of education, and the following letter, from Gen. W. H. Richardson, ably and vigorously seconds his views.

"Not having time to call on you this morning, I write to express my hearty concurrence in the suggestions thrown out in this morning's Enquirer, under the head of agriculture.

"My consideration of the subject, as you may well suppose, has not been very profound, and I am sensible that the conclusions to which it has led, are very far from being entitled to much weight. I have long admired the plan of the celebrated Fellenburg, to which you refer; and hough, as I still think, that one such school would be worth more than all the professorships of agriculture that could be established in our colleges. If the agricultural portion of our people could be awakened to their true interests, one such school at least could be established in each of the grand divisions of the State and sustained by individual subscriptions. Or, if not effected in this mode, and the financial condition of the State should not admit of the requisite aid from the public treasury, might not a tax be laid for that special purpose? It is difficult to estimate the advantages that might justly be expected from agricultural schools, in which theory and practice would go hand in hand, and where the mental as well as physical powers were judiciously cultivated. We all know, that the few landed estates which are yet left to be transmitted from fathers to sons, most frequently fall into the hands of young men just from college, who, though they may be fine scholars and qualified to attain the highest professional rank, are yet profoundly ignorant of that which it most concerns them to know—practical agriculture. So, too, of the least wealthy portion of our people, who train their sons to the labors of the farm, but most frequently in the same path which has been trodden by fathers, grandfathers and great-grandfathers before them, but upon which no one ray of improvement has yet been shed. These young men are, according to circumstances, either portioned off with small farms, or seek employment as overseers, having, generally, little else than habits of industry, with true and honest hearts, to qualify them for the business of life. It is easy to conceive, that to all these the education of an agricultural school would be certain independence, if not wealth.

"The want of sufficient skill in agriculture and farm management among overseers, we hear complained of by almost every farmer who employs one. It is a serious grievance; but the poor fellows themselves are not to blame, for they have no chance of better information. A case lately came to my knowledge of a lady, possessed of a good estate in land and negroes, who had been repeatedly disappointed in overseers, and at length employed one whose known industry and integrity it was hoped would suffice. But with a full stock of these indispensable qualifications, and every wish to give satisfaction, he proved so utterly ignorant of farm management, and of any standard of agriculture beyond that with which he had grown up—between the handles of an old style one-horse plough, with a wooden mould board, and rope traces—that his employer has a certain prospect of loss upon the year's work, and he of losing his place. An experienced and observant farmer lately remarked in my presence, that many who were now struggling in the over-filled professions, and the uncertain risks of commercial

pursuits, must soon find themselves driven to agriculture for a subsistence; and that, instead of every man who can command the means, sending his sons to fill the classical schools of the day, uncertain what they must do when they attain to manhood, they should be (or a large majority of them) trained in schools of agriculture, which the public voice should compel the Legislature to establish.

"Agricultural schools should be alike accessible to rich and poor, and in the vicinity of flourishing towns, might, as you have suggested, to a considerable extent, support themselves. To the rich they would be scarcely less valuable than to the poor; as the first would be taught how to improve and preserve his inheritance, whilst the last would learn how to acquire independence for himself and an inheritance for his children. Many farmers are most anxious to give their sons such an education; and even among the poorest and most ignorant, scarcely one could be found who would not cheerfully surrender the labor of his son for the advantage of placing him in an agricultural school. A very poor, but most respectable man applied to me early this year to take his son, a stout youth of sixteen, for five years, stating that he wished to make him a farmer—not to expose him to the vices of a town life—that he had nothing more to give him than he had already given, a plain English education—and as he hoped, good principles and good habits. It was not in my power to take the youth, and especially because I knew myself to be incompetent to teach him what his father wished him to acquire. Now, the labor of his son was worth something to the father, (a feeble man,) but he was most willing and anxious to give that up, and even to permit him to labor on my farm with my negroes, for the advantage he supposed would be derived from my instruction. It was an over-estimate of my qualifications—but serves to show the infinite importance to a large majority of our people, of agricultural schools.

"The press is the most powerful engine that can be brought to bear upon this important subject. I rejoice that you have taken it up, and hope that it will be pressed with your accustomed zeal. * * * * I trust too, that it will be taken up by the press universally. Half the devotion to this great cause, that the political press bestows upon the party politics of the day, would do more for the best interests of Virginia, I verily believe, than any thing besides. Our Society, there can be no doubt, will do its part.

"This is not written for publication. I am not qualified to discuss the subject in the public prints, and therefore, do not wish to appear vain enough to attempt it. Abler pens and more distinguished names than mine must do the work; and it is time that work was in hand.—Let the word be onward."

Industry.—Every young man should remember that the world always has and always will honor industry. The vulgar and useless idler whose energies of mind and body are rusting for want of exercise—the mistaken being who pursues amusement as a relief to his enervated muscles, or engages in exercises that produce no useful end, may look with scorn on the smutty laborer engaged in his toil. But his scorn is praise. His contempt is an honor. Honest industry will secure the respect of the wise and good among men, and yield the rich fruit of an easy conscience, and give that hearty self respect which is above all price.

Toil on then young men. Be diligent in business. Improve the heart and the mind and you will find the well-spring of enjoyment in your own souls, and secure the confidence and respect of all those whose respect is worth an effort to obtain.

Scours in Calves.—We have never, says the editor of the Southerd Planter, found any remedy for the scours preferable to boiled skimmed milk. This should be given warm, and it is more safe than poisons of any kind.

DUTIES OF FARMERS.

Among the many duties which devolve upon farmers, there is none of higher importance or to which is attached a greater share of responsibility, than that of affording to the rising generation the means of instruction, and the facilities for cultivating the mind. It is in vain we talk of improving the soil and elevating the standard of agriculture in this country, while the youth, the sons and daughters of farmers, are denied the privileges of education and moral culture, which every sound and thinking mind will admit are necessary to enable them to pursue their avocations with pleasure and profit, and to discharge in a proper manner their duty in the various relations of life.

The subject of education in schools is of vast importance to farmers, and may with propriety be discussed in an agricultural journal; but we intend in this article only to point out some of the errors and omissions of duty with which many farmers are chargeable in the education and training of those who are soon to enter upon the stage of action, and to whom the agricultural interest must look for its friends and advocates. Education does not consist solely in the knowledge gained at schools. The history of some of our most eminent men shows that individual exertion, when aided and encouraged by parental advice and aid, may be the means of acquiring a degree of knowledge and of reaching a position which the mere advantages of school could never afford. We here repeat, what we have often in effect said, that self-culture is more neglected among farmers than any other class of persons. It is time that there was a reform in this respect, and we are happy in being able to say that there is evidence of its commencement, in the desire of agricultural reading, which pervades to some extent the youth of this country. It is the duty of those having the care of youth, so to encourage the first appearance of these desires, as to form permanent habits, and a disposition for investigation, which always leads to valuable results.—That father who, when his son discovers evidences of a fondness for agricultural pursuits, and an inclination to store his mind with that information which may be derived from the experience and writings of others, withholds the means of gratifying these inclinations, places himself in an unenviable position and can blame no one but himself, if his son does not pursue that course of conduct which he could desire.—The youthful mind is never inactive, and if it is thwarted from its laudable inclination, will be very likely to engage in the pursuit of objects which it would be wiser to avoid. There is no subject on which the mind of young men can with more propriety be employed than in the improvement of agriculture, and we think the judgment of our readers will coincide with ours, when we say that the surest means of leading the mind to an investigation of agricultural science, and the best means of accomplishing objects or improvement, is to place before them publications which have for their aim the good of agricultural interest. Often have we heard the boy of twelve or fifteen years, urge his father to subscribe for an agricultural paper, which could be had for fifty cents or a dollar a year, promising to read it attentively, and in some instances to work out and earn the subscription money, while the father would utterly refuse to allow him the privilege of storing his mind with information, which might be the means of adding greatly to his usefulness, and prevent him from acquiring habits of dissipation and idleness. And why is this refused? Simply because it will cost a few shillings a year, while as many dollars would perhaps be freely expended on objects which can be of no possible advantage to the youthful mind. There are hundreds of such cases even in this enlightened community, and we wish in a respectful manner to call the attention of such individuals to the subject, and to show them the nature of the responsibility which they have thus voluntarily assumed. If we would elevate the character of the farmer, we must enlist the feelings of the youth, thus enabling them well to act their part in the duties to which they will be called. Were is the man who is willing to stand in the way of improvement, by keeping as far as his influence goes, the sons and daughters of farmers, ignorant of the means of improvement which shall be extended to them in their youth. Every opportunity should be embraced to impress upon young persons the advantages, as well as the respectability of agricultural pursuits.

When we hear a young lady, and the daughter of a farmer, say with an air of confidence that she cares nothing for the interests of agriculture, and that she feels far greater interest in attending balls, and dancing schools, than in reading publications devoted to the improvement of the business in which her parents have obtained an honest living, and perhaps amassed a fortune, we generally conclude that although the parents may know very well how to take care of dollars and cents, they must have neglected the education of their children, and are accountable for a violation of duty not only to their family, but to the circle in which the children are to move. We have heard young ladies openly avow the above sentiments, and have felt pained on accouut of their ignorance, while they supposed themselves well informed and well educated. We are happy, however, to say that a very great portion of the females among the agricultural portion of the community, exert all their influence in favor of rural pursuits, and that much of the spirit of improvement, which is now every where witnessed, as well as a great proportion of the interest which is manifested in agricultural exhibitions, may be fairly attributed to the influence of females. Let fathers and mothers discharge their duty in a proper manner, and educate their children so as to encourage rather than repress a fondness for agricultural pursuits, and the time will soon come when agriculture, instead of being looked upon with disdain, will engage the attention of the young and hold a high place among the occupations of life.

It is too often the case in this country, that young men instead of relying on their own powers of mind to investigate the different and varied subjects connected with agricultural pursuits, rely solely on the knowledge which their father can impart, and never dream of turning aside from the track which others have pursued before them.

We recollect on one occasion meeting with a farmer whom we invited to subscribe to our journal, and inquiring the price and the objects of the paper, he inquired of his son, a young man of perhaps sixteen or eighteen years, if he would like to have an agricultural paper, to which he replied that he wanted a paper that had funny stories in it. On our remarking that a knowledge of agricultural pursuits was of far greater consequence to a young man than a perusal of funny stories, he very promptly answered, "I can learn enough about farming from dad." We fear that this opinion is far too prevalent among the sons of farmers in this country, and that they rely more on Dad than on their own exertions. We ask farmers, and the friends of agriculture, to think of these things, and see whether their duty does not require that they place within the reach of the youth in their charge, information which shall enable them not only to make a proper choice of business, but which will qualify them for the proper discharge of the business of their choice.

Central New York Farmer.

Lice on Fowls.—In your October number, I observed some remarks on using sulphur to destroy lice on fowls. This I have tried in former years with entire success. Mixed with Indian meal and water, and fed in the proportion of 1 lb. of sulphur to 2 doz. fowls, in two parcels, a few days apart, I have found that it would soon exterminate the lice, and produce a remarkably healthy and glossy appearance in the fowls. They should at the same time be supplied with proper dusting places.—*Alb. Cult.*

FARMING WITHOUT RUM.

Whoever commenced the Temperance Reformation, was, in truth, a benefactor to the human race. From the highways and byways, from the borders of the abyss of degradation, if not from the depth of the abyss itself, thousands will rise up to call that man blessed, who has saved them from themselves. Great as are the talents of O'Connell, there is an unpretending priest, who is at the present moment doing more to elevate, disenthrall, and regenerate Ireland, than a thousand O'Connells, without his aid, could have done. Wherever Father Matthew goes, the distilleries become useless, the pig gets an extra quantity of corn, the wife a new dress, and the laborer sheds his rags for a new coat, saved from earnings that formerly went to brutalize and impoverish himself and family.—Scarcely less striking has been the result of abstaining from the common use of ardent spirits in the United States, and in no department of industry has this influence been more beneficially felt than in that of agriculture. Of this no one doubts, we believe, who has made the experiment of *farming without rum*, or in other words, banished ardent spirits from his farming operations.

We are well aware that there were thousands, in fact nearly every farmer in the country, who when the idea of farming without the use of ardent spirits was first proposed, deemed it wild and visionary, if not impossible. So intimate had the associations of work and rum become in the minds of most men, that to separate them —to undertake to break in upon long established usage—to get in a harvest, or erect a building, without such drinks, required no little exercise of reason and independence of feeling.—Many who were convinced the practice was useless, hesitated about abolishing it, least the withholding spirits should be charged to a penurious disposition. Good sense, however, and a feeling of right prevailed; rum was banished from the harvest field and the raising, in numerous instances, and it was found that none of the injurious effects anticipated by many, followed. There was no want of laborers; the coarse grains still commanded good prices; and four or five distilleries in every town ceased to produce and distribute misery and death.

In those neighborhoods, and on those farms from which intoxicating drinks have been banished, those revolting scenes unfortunately once too common, are now no longer seen. We remember when it was the custom to find each laborer in the harvest field with his pint of spirits daily, that there was frequently more waste from the effects of the drink than their labor cost. We have seen in the harvest field by the middle of the afternoon, the reaper so *blue* that he was as likely to cut his own fingers as the grain, and compelled to resort to a corner of the fence and a nap, to restore a capacity to work. We have seen half a dozen cradlers raeing it through a wheatfield like madmen, yelping and yelling like savages, throwing the grain behind them without care or thought, and causing a waste greater than as many swine would have done, even if they had been of the most approved alligator breed. We have seen a dozen men reeling home from a raising to sleep away the liquor that had stolen away their reason, or, as was most likely, to abuse their wives and children. Now, where temperance principles prevail, such scenes are never witnessed: and their influence can be traced in the mitigation of these evils, even where they are not yet fully triumphant.

The proper source of ability to labor is found in food; this alone nourishes and confers strength. Ardent spirits give no nourishment; they only stimulate; and experience proves, that all expenditure of power, not based on the true source of supply, can only be temporary, and must produce results the more injurious to the individual. The correct course, then, is to substitute the nutritious for the stimulant, healthful for the injurious, habits that too frequently end in ruin for those that are certainly safe and honorable.

If there is a single reader of the Cultivator, who has never made a trial of farming without rum, we ask him as a friend to make it thoroughly the present season, and then to judge for himself. The experiment is not now an untried and hazardous one; it encounters no opposing public opinion, nor subjects the farmer to the charge of eccentricity or niggardliness; and it is not one which might once have been considered as tampering with the health of the workingman. The man who labors must have food in abundance, and of the best kind; he must have drink too, but this should not be ardent spirit.—*Albany Cultivator.*

CULTIVATION OF CORN.

The Nashville Agriculturist gives the following directions for the cultivation of Indian corn The editor says:

"It is scarcely probable that we or others have learned all, or half, that is important in the cultivation of this crop, and therefore we can only promise imperfect directions; but such, if carefully adhered to, will be useful to most farmers."

1. *Preparation of Land.*—The richer the soil the better for corn; and if it be not rich, stable manure is the best remedy: indeed, any kind of decayed vegetable or animal matter will show as much in this crop as any other. The land should be broken as deep as possible—if from ten to twenty inches, so much the better. Stubble, grass, weeds and all kinds of litter should be turned under. If this can be done sufficiently early to let the frosts have their influence in pulverizing the clay and compact portions of the earth, it will be better. A good plan is to break the land, by throwing into beds from four to six feet asunder, in proportion to its strength. On this plan the beds for the roots are more certain to be light and open; and the best proof that this is a good system is, those who commence rarely abandon it.

2. *Time of Planting.*—So far as our experience goes, the earlier corn can be made to grow, the more certain is the crop. Generally there is a drought early in the summer which cuts the crop short; and the only sure remedy is to plant early. March planting, nine times out of ten, is the surest plan for the latitude of Tennessee, though occasionally good crops are raised, planted in April and even May.

3. *Manner of Planting.*—If the land has been thrown into ridges, a bull tongue, or a shovel plough in the centre of the ridge, drill the corn and cover it with a light harrow. If the land is broken with a level surface, it is a good plan to run a turning plough as deep as possible, and in this furrow run a coulter or other small plough, to make a soft bed for the young roots. These rows might be from four to five feet apart, in proportion to the strength of the soil. Cross these furrows at the same distance, but run the plough as shallow as possible. Drop the corn at the crosses, and cover with a hoe, light plough or harrow, to the depth of from one to three inches.

4. *After Culture.*—So soon as the young plants show themselves, run a cultivator near them to stir the soil and destroy the small weeds. If the land is now stirred every week, with a harrow, cultivator light plough, to keep down weeds and render the land open for the free access of the atmosphere, the crop will certainly be good.—Every one should be sure to thin out early.—Whether the land should ever after planting receive a deep ploughing, depends solely upon circumstances. If the land has run together from heavy rains, it should be ploughed—not otherwise.

MAKING MANURE.—Asa Barton, in the Maine Farmer, says that he converted straw, corn stalks and potatoe tops into good manure in 14 days, in the spring of 1841, only by heaping them together, and mixing unslacked lime with them. He used six casks of lime, and had fifty loads of good manure. The loads were such as farmers carry, a large half cord to the load.

MILKING COWS.

The owners of cows should pay particular attention to milking. Children must not be trusted with this business, and there are many grown people who never milk well though they have been brought up to the business.

If you would obtain all the milk from the cow, you must treat her with the utmost gentleness; she must not stand trembling under your blows nor under your threats. She may at times need a little chastisement, but at such times you need not expect all her milk.

Soon after the bag has been brushed by your hand and the ends of the teats have been moistened a little with milk, it flows in rapidly, and all the veins or ducts near the teats are completely filled. Then it must be drawn out immediately or you will not get the whole. You must not sit and talk—you must not delay one moment if you would have all the cow is then ready to yield.

The udder should be moved in every direction at the close of milking, and the hands may beat it a little in imitation of the beating which the calf gives it when he is sucking. An expert milker will make the cow give one quarter more in butter, than a majority of grown milkers will.

One season, at Framingham, we kept four cows in the home lot; there was but little difference in the quantity of milk given by each. We had a *very steady* hired man of forty years of age; he had carried on a farm in New Hampshire and always been used to milking; but he was so slow the cows had no patience with him.

We milked two of the cows and he the other two, and we were but little more than half as long as he in milking, though we got the largest mess by about one quart. On our remonstrating that he did not draw out all the milk, he said his cows would not yield so much as those milked by us. We then made an exchange: he milked our two and we milked his. In three weeks time the case was reversed; our mess exceeding his by nearly one quart. He never failed to strip his cows to the last drop; but his *intolerable moderation* prevented his obtaining what an active milker would have done.

Young learners may practice on cows that are to be soon dried off. They should be taught *at first* how to take hold of the teats and they will remember it; but how common it is to let each child choose his own mode of milking! Learners should know that the hand should be kept very near the extremity of the teat, if they would milk with ease. The left arm should always press gently against the leg of the cow; for if she is inclined to kick, she cannot with any force; she cannot *strike* an object that leans against her; but if she raises up her foot, as she often will when her teats are sore, the milker will be ready to ward off and keep it from the pail much better than when he sits far off from the cow.

If heifers are made tame and gentle by frequent handling when they are young, they are not apt to kick the milker; their udders should be rubbed gently before calving; it is quite as grateful to them as carding. But if they are suffered to run wild till after they have calved, they cannot be expected to be gentle when you first attempt to milk them. They often acquire bad habits and are not broken of them through life.—*Mass. Ploughman.*

PRESERVATION OF HEALTH.—An ancient philosopher once said, "If you find it necessary to have recourse to medicines, there are three which you can make use of with safety, viz: a tranquil mind, moderate exercise, and temperate diet."

The celebrated French physician, Dumoulin, on his death-bed, when surrounded by the most distinguished physicians of Paris, who regretted the loss which the profession would sustain in his death, said: "My friends, I leave behind me three physicians much greater than myself." Being pressed to name them, each of the doctors supposing himself to be one of the three, he answered, "water, exercise, and diet."

PROGNOSTICS OF THE WEATHER.

PROGNOSTICS FURNISHED BY THE HEAVENLY BODIES.

1. *Observations of the Sun—Signs of the Wind.*—The sun rises pale and remains red; his disc is very large; he appears with a red sky at the north; he maintains the color of blood; he remains pale, with one or more obscure circles or red rays; he appears concave or hollow. When the sun seems divided or is accompanied by a parhelion, it indicates a great storm.

Signs of Rain.—The sun is obscure and as it were bathed in water; he rises red, or with black stripes mingled with his rays, or becomes blackish; he is placed above a thick cloud; he rises surrounded with a red sky in the east. Sudden rains are never long; but when the sky is changed gradually, and the sun, moon and stars are obscured by little and little, it rains generally for six hours.

Signs of Fair Weather.—The sun rises clear, and the sky has been so during the night; the clouds which surround him at his rising take their course to the west, or indeed he is environed by a circle, provided that the circle is at equal distances on all sides; then we may expect weather constantly fair; he sets amidst red clouds, whence this popular saying, that "*a red evening and a gray morning are sure signs of a fair day.*"

2. *Observations of the Moon.—Signs of the Wind.*—The moon appears very large; she puts on a reddish color; her horns are pointed and blackish; she is surrounded by a distinct and reddish circle. If the circle is double or broken it is the sign of a tempest. At the new moon there is often a change of wind.

Signs of Rain.—Her disc is pale; the extremeties of her crescent is blunted. The circle around the moon attended by a south wind *portends rain the next day.* When the wind is south and the moon is visible only the fourth night, it portends much rain for the month.

Signs of the Weather.—The spots on the moon are very visible; a brilliant circle surrounds her when full. If her horns are sharp the fourth day, it will be fair till the full moon. Her discovery brilliant three days before the change or the full moon, always denote fair weather. After each new and full moon, there is often rain followed by fair weather.

3. *Observations of the Stars.—Signs of Rain.*—They sppear large and pale; their twinkling is imperceptible, or they are encircled. In summer when the wind blows from the east and the stars appear larger than usual, then look out for sudden rain.

Signs of Fair Weather and Cold.—The stars appear in great numbers, are brilliant and sparkle with the brightest lustre.

From the Farm House of the XIXth Century.

THE ROLLER.

From several years experience, I am fully satisfied the roller is an indispensable to good farming; and yet, I am as fully convinced, if not used judiciously, it will do much injury. There are but few rules necessary to be understood to construct a roller. Those made of iron, of course, are best; but as economy is a part of the farmers study, a wooden one will answer all the uses of the husbandman.

Take a stick of wood six feet long, and big enough to make a cylinder two feet in diameter; bore a hole through, and pass a bar of iron, to serve as an axel and support the frame work for hitching horses. If the roller be cut into two pieces, each three feet long, there will be no dragging in turning, and the seeds will come up more regularly at the ends of the lands. Almost any common carpenter or wagon maker might prepare a roller in a short time.

USES.—The roller is valuable on light sandy land; also it is admirable for breaking clods, will cause oats, wheat and all small grain crops to come up better, leaves the land smoothe and pleasant for reaping, and it is the best instrument for running over wheat tn the spring which has been frozen out. But if the roller is used on clay, particularly when a little wet, the ground will become packed so closely, that more than a season's ploughing will be required to become at all free and open. In conclusion, we must remind the inexperienced to be cautious, or they will regret that they ever saw a roller.

Tennessee Agriculturist.

METHOD OF CAUSING CABBAGES TO HEAD DURING THE WINTER.

In the fall of the year when it is time to gather cabbages, we always find more or less of them that have not formed any heads. They may have grown well, and have a large stock of leaves, but have not closed up in the form necessary to make a good, solid, compact cabbage.

William Vance, Esq. of Readfield, has practiced for many years the following method, which effectually closes these loose leaves in the course of the winter, thereby furnishing him with a supply of the best kind early in the spring. In the fall of the year, just before the ground closes up he gathers all the cabbages which have not headed together. He then digs a trench eighteen inches or more deep, and of sufficient width to admit the cabbages. He then closes the leaves together by hand, winding a wisp of straw or somothing else around them to keep them together, and then puts them in this trench, with heads down and roots up. He then packs straw or leaves and earth snug about them, and rounds up the earth over them. The trench should be dug in a place where the water of the rains and snows run off and will not stand about them. A board, or couple of boards, nailed together in the form of a roof and put over the mound, may be useful.

In the spring of the year open your trench and you will find that the cabbages are all headed firmly together, and if the water has not got in, will be solid and hard. Mr. Vance has had the goodness to send us a few heads which he has formed in this way, which were very nice. By following this plan, we not only preserve the cabbages well during the winter, but save much of the crop which is not considered worth much.

Maine Farmer.

CULTURE OF THE STRAWBERRY.

I early turned my attention to Horticulture, and in one department of that, the cultivation of strawberries, I think I can show by facts that I have been truly successful. I have not failed to have a good crop every year, for ten years; and last year, from 1371 plants only a year old, I sold eighty gallons, besides what was consumed in my family, and some choice parcels, perhaps from vanity, sent as presents to my friends. My garden is a light loam, nearly level, but high and dry, not remarkably rich, it having been taken from a wheat field and enclosed the year before.

My mode of cultivation is to set out the plants or runners at equal distances of 18 inches, and if planted in the spring, keep them constantly worked and the runners off. This may be done with a garden scraper, quickly and neatly. In the month of November, if the season does not set in cold sooner, I manure with well rotted manure and work it in, putting my beds in nice order. I then cover them about one or two inches deep with pine shatters, (having an abundance of them,) straw, chaff—perhaps tanner's bark would do as well, though I object to the chaff because it has more or less wheat, which will vegetate, and give your beds an unsightly appearance. Having made my servants work the shatters under the vines, they stay on until the strawberries are done bearing. In this way the vines are kept warm in winter, the grass and weeds do not spring up, and the fruit is so clean when gathered, that there is no necessity of washing, &c. I make no alleys in my beds, my ground being porous and dry. If I plant in the spring, I deem it advisable to renew my beds after the second year's bearing. This is done by simply directing the runners to the centre of the square formed by the old vines, throwing over the tendril of the runner a little earth, to keep it in place, and when the runner has taken root, sever it from the parent vine. Then with a hoe, for the space will admit it, cut out the old vines. The manure which the ground has received in two years, will put it in fine order, and thus the bed may be kept up for years. I intend to try plaster on my vines this spring. I sold my strawberries for 50 cents a gallon, throughout the season, in our village market, and could not gratify the demand. I omitted to state that the 1371 plants grew on a comparatively small area, as any one may see by calculating it. I then had four beds. I now have twelve, and in every bed the plants look beautiful, scarcely one missing. I have but very few male plants, though it was by accident.

BRICE J. GOLDSBOROUGH.

Albany Cultivator.

VALUE OF SEASONING FIRE-WOOD, &c.

We make the following extract, says the Southern Planter, from a letter received from Mr. George W. Craven, of Albemarle.

"Perhaps, gentlemen, I can throw out a useful hint (whilst I sit by a cheerful *seasoned* wood fire,) on the importance, comfort and saving of labor by having seasoned wood instead of green. In the first place, it does not require more than half the labor to load and unload, and half the labor to haul, which is no small consideration. And then half the quantity of seasoned wood makes as good a fire; for two or three sticks of seasoned wood makes a good fire, and you get the benefit of the whole of it, as none goes off in smoke to make foul chimneys. For smoke is nothing more nor less than unconsumed fuel. Therefore, I would advise all farmers to cut their fuel the winter before it is used; split and set it up. If for market, no one that considers comfort and economy will object to it because it is seasoned. It is a fact, that any wood, when seasoned, makes a good fire, whereas, there are many kinds of green wood that make an intolerable one. For instance, pine wood green will scarcely burn at all—when seasoned, it makes a respectable fire. All kinds of timber are better for being seasoned. If farmers would cut and split their stakes there would be no need of burning. Fencing and hauling is more expeditiously done when the rails are seasoned. I consider one of the greatest secrets in farming is a judicious saving and application of labor in the various operations of the farm. For labor saved is money made. I have spent some $50 in the last twelve months (as hard as the times are) in labor-saving machines, and consider the money not badly spent. In the first place, it occurred to me that a great saving of time and labor might be made in the tedious process of shelling corn by hand. I therefore had a machine made with no extra work but a whirl for the machine band to run on, cost, $12 50. I can in ten minutes detach my machine (threshing box) and attach my corn sheller, and in a day, I can shell corn sufficient to last man and beast for a month or more, with but two horses and two men and a boy to drive. I also had a straw cutter made with the same extra work, a whirl, cost $25, which I can attach to the same machine in five minutes, and cut straw enough in one rainy day to last several weeks for some twelve head of horses and as many cattle. So you see it is not only a saving of labor but you do it all in bad weather with but few hands.—And then when the weather is fair, I have no hindrance of this kind to delay my work, but go right ahead, from morning until night, and no stopping to shell corn and cut feed. I cut up every thing for my horses (or rather I make them do it,) and I never allow an ear of corn to go in their troughs until it is ground and mixed with some kind of cut straw or chaff. In the winter months, I have my servants' breakfast prepared for them while they are feeding, so that they do not go to work before sun-up in cold weather, which I consider a saving of time, for they cannot do much in cold weather before breakfast."

AGRICULTURE is the most ancient, the most honorable, and the most useful of arts.

WEDNESDAY, APRIL 12, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

FARMERS' ENCYCLOPEDIA AND DICTIONARY OF RURAL AFFAIRS.

We have received the three first numbers of this truly valuable publication, and respectfully recommend it to the planting community. It is an English publication, revised and adapted to American agriculture. The numbers before us are better arranged than any work we have seen, by which reference can be had to any subject with the same facility that a word may be found in a common dictionary. It is published semi-monthly, by Messrs. Carey & Hart, Philadelphia, and will be completed in sixteen numbers, at 25 cents a number. The work is got up in a very neat style, in book form, and when completed, will be very valuable as a work of reference on all subjects of which it treats.

HORIZONTAL PLOWING.

We have to thank our friend HUNT, for his communication on the subject of horizontal plowing, and hope he will continue to forward such facts as he may deem of value to his agricultural brethren. We have endeavored to make a cut of his level, which we hope will be comprehended by our readers, for, in the absence of any engraver, our only reliance has been upon ourself. This is one of the difficulties under which we labor; for we shall be compelled to send abroad, perhaps to the north, for all our cuts. Though if the planters will sustain us with a liberal patronage, no expense shall be spared to afford every necessary embellishment to render the Cultivator equal, in this regard, to any Agricultural paper in the Union. We shall, therefore, in due time, if our subscription list will justify the expenditure, make such arrangements as will enable us to present proper cuts of all the most approved agricultural implements now in use, together with such improvements and new ones as may from time to time be introduced. We sincerely hope we are not too sangine, when we indulge the confident hope that Southern planters will sustain our enterprise most liberally, and enable us to build up a work, of which the South may justly feel proud.

We encounter the same difficulty in complying with the request of our correspondent, to "give some idea of a Cultivator," for the want of a proper cut, and are, therefore, compelled to rely upon the following description of that valuable plow, which we find in the Albany Cultivator.

CULTIVATOR.—This is an implement of agriculture, the use of which is to loosen the earth between rows of plants, so as to destroy weeds, and give the earth and plants the benefit of atmospheric influence. It is formed of a central piece of timber with diverging moveable side pieces, into which shares or points of iron are fixed, and the whole, drawn by a horse, pulverizes and stirs the earth, without penetrating so deeply as to injure the roots of the plants under cultivation, as is sometimes done by the common plow, particularly in crops of corn and potatoes. In preparing these plants for hoeing, the cultivator is now generally used in preference to the plow, as possessing all the advantages of that implement, with none of its disadvantages. As with the plow, so with the cultivator; a great variety of these implements have been placed before the public, the general principle in all the same, and differing only in the details and construction.

For the Southern Cultivator.

COLUMBIA COUNTY, April 10.

Messrs. EDITORS—The following is a preventive to the destruction of cabbage plants by the cut worm:

Take of China berries, boil them until a strong decoction is made; pour one gill at the root of each plant, and the worm will leave immediately. I have tried the remedy for many years. It has never failed. If the above recipe be worth publishing, you can do so under the initials. J. C.

For the Southern Cultivator.

TRAQUILLA, JONES COUNTY, April 3d.

Messrs. EDITORS—Noticing in the third number of the Southern Cultivator, under the head of "Agricultural facts," a request that every farmer and gardener, whose eye met the heading of that article, would send you such facts as he may be in possession of, relating to agriculture, I have thought proper to send you an experiment of mine in "*horizontal plowing*," which I have not seen noticed by any other in your paper, and which I am fully persuaded must be adopted by our planters, if a better plan cannot be suggested, to secure our lands from washing.—My own experience in this mode of plowing has satisfied me that it is much better than the system, so generally in use, of up-hill and down-hill plowing and planting, and if carried fully into effect, our hilly lands may be saved from washing almost as well as the level. I will now give you my plan as well as I can describe it, and depend upon you to correct bad spelling and grammar, as I am no grammarian.

FIRST—I make a level (the form given below) 15 feet at the base from foot to foot, braced across about 12 or 18 inches above the base; and after placing it on a level foundation to ascertain the center of the brace, by the aid of a plumb attached to the point, I then place a 3 inch block under one end of the level, so as to get the guage, indicated by the line of the plumb, on the brace or cross piece, to give a fall of one inch for every five feet. This done, I am ready for laying off my land.

In laying off, my plan is to commence on the point of a hill, so as to drain the water each way. Care should be taken, that the water be not carried too far before it is let off in ditches or outside of the field, to prevent the collecting of the water in so great a body as to wash the rows,—all of which, should have precisely the same fall as the water-furrow, (I call every row a water-furrow,) a result easily attained by the careful and frequent application of the level.—Should there be small sinks or gullies, they should be filled, to admit the water to pass over them—otherwise, it will collect in a body and break across, forming a wash carrying off the soil and growing crop. Should the hill-sides be abrupt, ditches should be cut at such distances apart, with sufficient fall, to take off the water gradually,—the direction of which, will be readily indicated by the use of the level, which enables you to give the ditch its proper direction without difficulty. In laying off the rows between the ditches, my plan is to commence on one side, and lay off half way, then commence on the other side, by which the short rows, if any, will be left in the middle,—which is very desirable, as it prevents the destruction of the margin of the ditch in cultivation. Sometimes, however, it is best to make the short rows nearer one side than the other, owing to the situation of the land,—a fact which the practised eye of an experienced farmer will readily perceive.

In the construction of your level, care must be taken to make it light—a small boy, with a hoe, will answer to mark every place where the level stands; and, after running the row, these marks or chops should be followed back, as it is impossible, on bumpy land, to run the rows correctly, if there is very material variation—although a slight variation, occasionally, is allowable to give the rows a better shape or curvature.

I have thus, as briefly as I can, given you my plan for preventing the washing away of rolling lands,—which, if adopted generally by the planters in Georgia twenty years ago, I have no doubt the lands would be worth one hundred per cent more than they will now command. If you deem it of any value, it is at your service—and any other facts I may deem worth publishing, you shall have.

Yours, respectfully,

THOMAS HUNT.

P. S.—Be so good as to give an idea of the plow called the cultivator.

"DIG ABOUT AND DUNG IT."—This direction was given many centuries ago, and has often been repeated, and perhaps I may say, as often forgotten or neglected. Last summer I took particular care to apply the above to some young pear trees. One was a graft of a year's growth, on a stock of several years' standing. The ground was loosened for some distance about the tree, perhaps a dozen times during the season. From a single stem of three feet, the new growth measured 30 feet! The effect on all was very obvious.—*Albany Cultivator.*

MAXIM OF HEALTH.—Sir William Temple says:—"The only way for a rich man to be healthy is to live as if he was poor, using exercise and observing abstinence."

A GOOD COW.

The following song, descriptive of the points of a celebrated Durham cow, was chaunted amidst great applause at the Darlington Agricultural Society's meeting.—*Gateshead's Obs.*

She's long in her face, she's fine in her horn,
She'll quickly get fat without oil-cake or corn.
Hurrah! hurr. h for this beautiful cow!

She's clear in her jaws and full in her chine,
She's heavy in flank, and wide in her loin,
She's broad in her ribs and long in her rump,
Has a straight and flat back with never a hump
Hurrah! hurrah for this beautiful cow!

She's wide in her hips and calm in her eyes,
She's fine in her shoulders and thin in her thighs,
Hurrah! hurrah for this beautiful cow!

She's light in her neck and small in her tail,
She's wide in her breast and good at her pail,
She's fine in her bone and silky of skin,
She's a grazier's without and a butcher's within,
Hurrah! hurrah for the beautiful cow!

SALTPETRE IN MEAT.

In the 12th number of the last volume of the Cultivator, there appeared a communication on the use of saltpetre in curing meat, and the following reason was assigned for abandoning its use, viz:—"It ought to be known, that saltpetre absorbed by the meat, is *nitric acid*, or *aqua fortis—a deadly poison*, whereby our salt meat becomes unpalatable and pernicious, a sufficient answer to which is found in the fact—that one of the constituents of common salt, is muriatic acid, as deadly a poison as the nitric acid of the saltpetre, and we might with as much propriety say, that the salt absorbed by the meat is muriatic acid, as to say that the saltpetre is nitric acid or aqua fortis. Therefore, the objection applies with as much force and truth to the use of the one as the other.

Saltpetre is the production of a chemical union between nitric acid and potassa, (potash,) and salt, of a like union between muriatic acid and soda—and in these, as in all other cases of chemical combination, the substances combining not only lose their properties, but the substances produced generally possess properties entirely different—frequently the very opposite of those of either of their constituents. From which it follows, that a perfectly innocent compound may be produced by the combination of two noxious substances—or a noxious compound by the combination of two innocent substances; and it is very improper, and well calculated to mislead, to designate a compound substance by the name of either of its constituents, as in the communication referred to, in which nitric acid and saltpetre are several times used as if they were but different names for the same thing.

Some persons think a small quantity of saltpetre very beneficial to their meat—others think it useless—the former need not be frightened from its use by the fear of being poisoned with aqua fortis—nor the latter deterred from trying it.—*Albany Cultivator.*

CURE FOR FOOT ROT IN SHEEP.—I take the liberty of sending you the following very simple remedy for foot rot in sheep.

I had occasion to procure a Spanish Merino Buck, a few months ago, from a distant part of the country, and on going into my sheep yard soon afterwards, I found him very lame in two of his feet, so much so as scarcely to be able to walk. I immediately removed him to the barn floor, and on examination found that his lameness was occasioned by that scourge of the Ovine race—the foot rot. I cleansed the hoofs thoroughly with warm soap suds, and fled to my books for a remedy. I soon found in the "Complete Grazier," p. 165, several remedies for this disease, but as I had not at hand the ingredients of which they were composed, I laid aside my books, and took down that "cure all," among farmers, my bottle of spirits of turpentine, and with a feather applied it to the parts affected, quite plentifully, twice or three times, in the space of three days, (keeping him upon the dry floor,) when I found that a perfect cure had been effected, and put him with the flock again, and have seen nothing of the lameness since.

Now, Messrs. Editors, this is a simple remedy, and found in every farmer's medicine chest, and I can safely vouch for its efficacy.

J. R. SPEED.
Albany Cultivator.

FATTING SWINE.—The food of swine is as much better for being cooked as the food of man. It is more palatable, more healthy, and much more nutritive. The digestive powers of swine are not as easily deranged as those of man, and the former can digest food which the latter cannot. Yet there is great economy in fatting swine on cooked food. Like man, they require a change of diet for health and thrift.—From our own experience we have come to the conclusion, that there is a saving of one quarter of the food—more particularly in the article of corn. Some farmers have said that there is a saving of one-third in soaking it for horses. But instead of grinding, scald your corn until it becomes soft, and salt it to your own taste. If your hogs lose their appetite, as they frequently do, by feeding steadily on one sort of food, give them a change for a few times, and they will eat greedily of the old dish again. Let their trough and feed be kept clean, and their lodging dry and warm, so that, as Cobbett says, you would be willing on a pinch of a stormy night, to turn into it yourself, if you could not find a better place. This mode of fatting is very agreeable to the swine, and economical for the feeder. If every farmer in our country will adopt our directions, what an immense annual saving would it be to the nation.—*Exchange Paper.*

TRUE FEMALE NOBILITY.—The woman, poor and ill clad as she may be, who balances her income and expenditure—who toils and sweats in unrepining mood among her well-trained children, and presents, them morning and evening, as offerings of love to her husband, in rosy health and cheerful cleanliness, is the most exalted of her sex. Before her shall the proudest dame bow her jewelled head, and the bliss of a happy heart dwell with her for ever. If there is one prospect dearer than another to the soul of man—if there is one act more likely to bend the proud and inspire the broken-hearted—it is for a smiling wife to meet her husband at the door with his host of happy children. How it stirs up the tired blood of an exhausted man, when he hears a rush of many feet upon the staircase—when the crow and carrol of their young voices mix in glad confusion—and the smallest mounts or sinks into his arms amidst a mirthful shout. God! it was a hallow from every countenance that beamed around the group! There was joy and a blessing there.—*London Journal.*

IMPORTANT TO FARMERS.—Hart Massey, Esq., of this village, took a small portion of the seed corn with which he planted a field, and soaked it in a solution of salt nitre, commonly called saltpetre, and planted five rows with the seed thus prepared. Now for the result; the five rows planted with corn prepared with saltpetre yielded more than twenty-five rows planted without any preparation; the five rows were untouched by the worm, while the remainder of the field suffered severely from their depredations.

We should judge that not one kernel saturated with saltpetre was touched by the worm, while almost every hill in the adjoining field suffered severely. No one who will examine the field can doubt the efficacy of the preparation. He will be astonished at the striking difference between the five rows and the remainder of the field.

Here is a simple fact which, if seasonably known, would have saved thousands of dollars to the farmers of this country alone in the article of corn. At all events, the experiment should be extensively tested as the results are deemed certain, while the expense is comparatively nothing.—*Washington Standard.*

FOR CORN—A RECIPE.—Mix plaster, unleached ashes, and quick fine lime together, in the following proportions:—two parts plaster, two parts ashes, and one part lime, and apply a small quantity of the mixture to each hill of corn immediately after the first hoeing, and see if it don't go a "leetle" ahead of any thing you ever tried to make corn grow. Be sure to leave one row without the application, "jest" to see the difference.—*Con. Farm. Gazette.*

AUGUSTA MARKET.

TUESDAY P. M., April 11.

Cotton.—The market during the latter part of last week was quite animated, and prices rallied till an advance of ¼ to ⅜ cent was obtained for all descriptions, upon the prices which ruled during the two first days of the week. Yesterday and to-day, however, the feeling has been rather easier, and the tendency is rather downward, yet we quote at the advance rate of the latter part of the week, 4 to 6¼ cents, extremes—principal sales 4¼ @ 5¼ cents; remarking, however, that these rates were not so readily obtained yesterday and to-day as a few days previous.

Trade and Business.—Since our last, spring has opened upon us, and the business parts of the city begin to assume that quiet appearance which denote the presence of the planters among their fields, preparing for the new crop. There have, therefore, been few arrivals of planters during the past week, and consequently a limited trade has engaged dealers.

Exchange.—The market is abundantly supplied with exchange, which continues at par on all points north and east of us. The amount of Central Bank money offering is not very large, and the sales range from 27½ to 30 ℔ cent discount—we hear of no sale below our lowest figures. State 6 ℔ cent Bonds are in demand, and command 50 cents in the dollar very readily. Alabama notes are from 20 to 25 ℔ cent discount.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., APRIL 19, 1843. No. 7.

PROGRESS OF IMPROVEMENT.

The *progress of improvement* in agriculture, though gradual, is yet steady. The importance of this branch of industry is beginning to be more and more appreciated. The whole country is more or less interested in it, as it furnishes, besides what is consumed at home, at least three fourths of all the exports of the United States. The vast public domain of unsold lands, too will be affected by this progress, and its value proportionably advanced. It may be well here to mention some of the principal sources of this improvement.

CAUSES OF IMPROVEMENT.

The *geological surveys* ordered and in progress, or recently completed, in many of the States, besides the other important benefits thereby conferred on those States, have contributed much to advance the science of husbandry.

These, in connexion with the experiments of agricultural chemistry, by thus directing the attention to their analysis, are developing the nature of the soils and their adaptation and means of increased production, by different seeds, products and methods of cultivation and manures, and so enable the farmer or planter to use the varieties of his land to the best advantage.

The increasing number of *agricultural periodicals* and treatises, and their cheap and more extensive circulation throughout the land, are also producing a happy effect. The farmers and planters in the various sections of our country are thus brought acquainted with each other's operations and success, and also with the methods of cultivation and rearing of stock, &c., common in England and on the continent, new products and the result of their trial are noticed, and the knowledge of many useful discoveries thus extended. The prejudice against "book farming," as it has been termed, which has so long proved a barrier to the adoption of valuable improvements thus suggested, is gradually wearing away; and a happy combination of science and practical skill is thus secured, the results of which are every year becoming more and more apparent.

Agricultural societies also exercise great influence in furthering the progress of agricultural industry. These are of but comparatively recent date, and their institution and increase in number and prosperity serve to mark the progress of improvement in agriculture; and if still further aided by an efficient board of agriculture, like what exists in Great Britain, they would no doubt be yet more successful. It is only about fifty years since that board was there established, and it has proved of extensive benefit to that active empire. By means of these societies, great numbers of the agriculturists of our country are brought together, to compare notes, as it were, to observe each other's success, and to converse on the topics connected with this branch of industry. They examine the machines, implements, animals and products offered for exhibition, and are induced to bestow more care and labor in the selection of their seeds and stock, in the preparation of the soil, and in their tillage and harvesting. Every year new and valuable improvements are thus made known and introduced, by which many are essentially benefited. Premiums also encourage to effort, and a highly salutary incentive is furnished, in the honor to be acquired of successful and approved farming. A similar effect, too, results from the bounties given by the different States to encourage the culture of some particular product. These have never been offered without a new impulse being stirred, and leading to increased attention to the pursuit.—Some of the States in these respects are far in advance of others, but almost all are beginning more to appreciate their true interest, and seeking to extend their true prosperity.

While adverting to the causes of general improvement in the agriculture of our country, it may not also be improper to allude to the increased habits of *temperance and sobriety* of the laborer, by which the condition of the farm-house and farm is so essentially benefitted, and domestic happiness and effective strength promoted. A clear head and a vigorous frame, in combination, will ever be most successful in tillage, as in every branch of industry. The lengthening of life and the repair of health, thus secured, render many who have been but drones and mere consumers, also active and efficient producers, as well as healthful consumers. The amount added, too, in the increased skill, as well as the saving from less breakage of tools and machinery of labor, and the actual effectiveness of such laborers as have heretofore been drawn from the intemperate class, now reformed, constitute no small item of gain in this view of the subject. No little damage has been thus sustained in the "inebriate" management and cultivation of the land, which is now avoided. Were this the proper place, some most interesting deductions might be made as to the physical force and efficiency thus added to the various branches of industry, and the bearing of the whole on agriculture, as a source of our national wealth.—*From Mr. Ellsworth's Report.*

IMPROVEMENT OF FARMS.

Plants as well as animals require food, which they obtain from the atmosphere and the soil.—When land is naturally barren, or is impoverished by severe cropping, it can only be improved by good tilling and manure. In looking over our farming districts, we find as a general rule, that farmers do not appreciate the value of manure; but few take the trouble of informing themselves of its true nature, and upon what its peculiar effects upon the growth of plants depend.

Manure is made up of certain gases, a few chemical salts, and some other less important substances, which, when placed under favorable circumstances undergo certain changes, which fit them to afford what is requisite for the perfection of plants. When the chemical changes in decomposing substances are taking place, gases are formed which are sensible to the smell; upon these the most valuable quality of manure depends; we consequently see the importance of putting manure in a situation where the gases may not be lost, either in a compost heap well covered with substances which have an absorbing power, such as charcoal, common earth, &c., or with something that will by a chemical change give off what would be useless or hurtful to plants, and take up what is beneficial in its place. Plaster of Paris, potash, soda, common salt, &c., act in this way. Sometimes there is contained in the soil in a latent state, as much nourishment as would supply all the plants that could be raised on it for a long time, providing there was employed some chemical agent to liberate it. This accounts for the wonderful effects of lime in some cases.

All animal and vegetable substances contain the elements of plants; nothing therefore on a farm should be lost. If a farmer wishes to add speedily to his productions, he must convert every refuse substance into manure. The mere manure he has, the greater will be his crops, and after a farm is once in good order, it is very easy to keep it so. Hundreds of substances are thrown aside and wasted, which would add to the quantity and improve the quality of the manure heap.

Manure is the laborer's friend; it makes the ground more easily tilled, and pays invariably for itself. In other countries they use much manure, for it is the only way they can produce the abundant crops that reward them for their labor. Every farmer should have a compost heap, into which he could put all his manure from his stables, and also deposite all his weeds, ashes, house slops, dead animals, feathers, rags, mortar, shavings, leaves of trees, &c.; and this should be constructed on a side hill if possible, that everything could be thrown in easily from above, and an opening left from top to the bottom on the lower side, so that it could be closed with boards shoved in proper grooves, which could be taken out separately, to facilitate the removal of the compost. Land is always best when it contains a proper proportion of clay, lime and sand, with a suitable quantity of animal and vegetable manure. When either of these is wanting, it should be added, for it has been found that such additions have produced the most beneficial effects.

Our undivided attention should be paid to the improvement of the land we have under our care. If we employed more thought and reflection in our farming operations, and used the means in our power with more sound judgment, then could we expect to see the best results following our exertions. If farmers would commence a series of experiments on a small scale at first, and when they ascertained what would best answer their purpose, then pursue it, they would soon find how much more valuable and productive they would make their farms. There is no question but that one of our greatest misfortunes is, that we have too much land; we do not value it sufficiently; we do not properly attend to it. There are but very few who have ever put their lands to the test, to show what their powers are. A system of robbery exists over the fairest and most eligible land in our country; and when the land becomes partially exhausted, the husbandman, instead of improving his farm by good cultivation, and the application of a proper kind of manure, concludes to sell out and purchase another farm where land is less expensive and more productive—a very bad practice, frequently bringing sorrowful disappointment from the severing of family ties and old associations, and also from blasted pecuniary expectations.

Such a spirit is manifested in every part of our country; even in Dutchess, one of the most productive counties in this State, we find that many farmers are becoming dissatisfied with their healthy and favorably situated farms, and are emigrating to other States, where much uncertainty exists whether the climate will agree with them, or if they will ever receive sufficient

returns to satisfy them for the sacrifices they must make. If such farmers would commence improving their lands, beginning on a small scale, they would soon find, that owing to the greater prices obtained for their produce in this market, they could compete with the farmers of any State of the Union, and would remain eligibly situated in a healthy country, having all the benefits of a long established society of well-bred and intelligent people.

HENRY A. FIELD, M. D.

New York, March, 1843.

American Agriculturist.

SALT AS A MANURE.

The testimonies in favor of salt as a destructive to noxious insects and favorable to vegetation, multiply upon us. The great desideratum in regard to the application of salt, is to ascertain in what quantity it should be applied; for while a certain amount is of universally acknowledged utility, an increased quantity is pernicious. Repeated experiments only can determine this. These are in progress both here and abroad. These analysis may be found, some of them in Turner's Chemistry; others, and very much at large, in Johnson on Fertilizers; and the whole subject is fully and admirably treated in Dana's Muck Manual for Farmer's, a book which we beg leave to recommend strongly to our inquiring correspondent, E. V. W. D.—*New Genesee Farmer.*

LAFAYETTE, Onandaga Co., N. Y., February 23, 1843.

DEAR SIR—Having, during the past summer, heard numerous complaints about corn-fields being devastated by the grub-worm, I will describe to you the precautionary means that I make use of for the extermination, not only of them, but of every worm that infests our fields, and at times make such great havoc with our crops.

Having frequently been under the necessity of replanting corn, and as often been troubled with unmarketable potatoes, from the ravages of the angle-worm, I was induced to try what effect salt would have on them. Before its trial, I had no doubt that a sufficient quantity would destroy all insects; but I was fearful that, at the same time, it would destroy vegetation too. Yet I was determined to hazard the experiment.—Accordingly, last spring, about twelve days previous to planting, I sowed five barrels of salt, broad cast, on five acres of ground; and planted the field, three acres with potatoes and two with corn. Among the corn I discovered only one stem at all injured by the worm. The corn, however, did not produce more than an average crop. The potatoes, however, did much better. From the three acres I obtained 1260 bushels of fair, good sized, smooth, marketable potatoes. The ground was in good order, and planted to potatoes the year previous. The result I attribute mainly to the use of salt.

That salt will destroy vegetation, I now have reason to doubt, (unless applied extravagantly,) by experiments that I made last summer. In a portion of the wheat-field where I had sowed nine varieties of wheat, I applied, at the time the stems were five or six inches high, salt, at the rate, I should think, of two barrels to the acre. None of the grain was destroyed; and yet I saw no benefit from the application. The whole field was badly shrunk, that portion as well as the rest. The other trial was upon some Canada thistles. To each of several stems I applied a handful of salt; and the only effect that I could perceive, was that it made them grow more vigorously. I applied it frequently and in large quantities to a patch of chick-weed growing in the garden; and was equally unsuccessful. The bed would wither down for a few days, and then rise up as vigorous as ever. The effect of brine, however, is different from that of salt. Wherever I have applied that, it has immediately destroyed all vegetation within its reach.

I am, myself, so well satisfied with the beneficial effects of salt in destroying insects, that I intend to sow it upon all of my meadow land this spring, at the rate of one barrel to the acre. Upon one-half of my wheat field, I sowed salt at the above rate, last fall, a short time previous to sowing the wheat. It looked well during the late thaw; but its effects, whether favorable or unfavorable, are yet to be seen. I use salt pretty much as people use Brandreth's pills—as a sovereign and infallible remedy for every ill the earth, as well as flesh, is heir to.

It gives a healthful appearance to peach trees—it invigorates asparagus beds, and it is almost incredible what quantity can with perfect safety be applied to their roots—when thrown into the heads of cabbages, it promotes their growth, and effectually destroys those ill-shaped, green insects that so often destroy them. Horses, cattle and sheep apparently know its beneficial qualities upon themselves; while hogs, with a little patience and perseverance, can be made exceedingly fond of it. At the present price of salt, it is within the power of every one to try at least one experiment with it. How many will do so the ensuing spring, and report success to head-quarters? E. V. W. DOX.

P. S. By giving us an analysis of the following articles, you will I presume confer a special benefit upon every reader of your valuable journal. The object of the analysis will be, to enable us to make more judicious applications of manures, both as to quality and quantity, than we are generally in the habit of doing.—Every farmer knows that manures operate very differently; yet our experience has not extended much beyond the use of gypsum, lime, and the manure of horses, cattle and hogs. I have often heard it said that, in order to raise red peppers, the product of the hen coop must be used. That it is effectual, there remains no doubt; but why it is so, I have never yet been able to explain. Or why is it that gypsum has so much effect upon clover? Why does unleached ashes benefit timothy, more than leached ashes? In fine, why does it benefit it at all? A table of the analysis of the various manures, together with that of the different varieties of grain, ought to be constantly before every farmer. He will then be able to decide at once, from a knowledge of his means, what kind of grain to sow.

The articles contained in the following list can be easily obtained at almost any place, provided they should be found serviceable;

Salt	Swamp Muck,
Gypsum,	Lime,
Wheat Bran,	Hen Dung,
Leached Ashes,	Horse "
Unleached Ashes,	Hog "
Rotten Wood,	Cattle "
Sheep Dung.	

E. V. W. D.

We have been kindly favored by Dr. Penney, editor of the Evening Post and the Western New Yorker, with the following communication, containing most if not all of the information sought for by the above correspondent:

ANSWER TO AGRICULTURAL QUERIES.

SALT—is in chemical language, Chloride of Sodium—that is, a combination of the gaseous substance chlorine, with the metal (or rather metaloid) sodium, in the proportion of 60 per cent of chlorine.

Sodium united to oxygen forms caustic soda.

" " to carbonic acid, carbonate and bicarbonate of sodo.

" " to sulphuric acid, sulphate of soda, an excellent article for clover and the pea kinds; costs in England 10s. per cwt.—is made from common salt, by adding sulphuric acid.

" " to sulphur, sulphate of sodium.

" " to phosphoric acid, phosphate of soda.

The component parts of salt are found in most plants, and therefore must be in the soil that bears them. If 25 tons of turnips be taken from an acre, there are removed from the soil 64 lbs. of soda and 14 lbs. of chlorine. If red clover, 12 lbs. per ton of soda. If 25 bushels of wheat, 3½ lbs. in the grain and about 1 lb. in the straw.

Salt sifted into your manure heap in layers, combines with the ammonia, one of the most fertilizing substances of the farm yard which is ever escaping, making muriate of ammonia and carbonate of soda, both valuable articles: the first affords food to the most valuable plants, the second is a most powerful solvent of vegetable fibre, and consequently a most valuable agent in preparing the manure for the nourishment of crops. As to quantity, say a peck once a week on the farm yard manure of a farm of 150 acres.

The other combinations are sulphate of sodium, carbonate of soda, (soda of the shops,) the sesqui-carbonate, and bi-carbonate, the caustic soda, (produced when common salt and lime are mixed in compost) and different phosphates of soda, which are found in the ashes of nearly all plants.

Experiments are reported by Johnson, made at Eske Hale, (Eng.) by a Mr. Fleming, in 1841, whereby it appears that the application of six bushels per acre of salt to grass land, on a high, bleak, thin, and light soil, increased the produce from two tons 12 cwt. to three tons 12 cwt. per acre.

GYPSUM—is in chemical language, the Sulphate of Lime, or a combination of sulphuric acid and lime.

Common Limestone, Chalk and Marble, and carbonates of lime. Quick lime is the combination of the base of lime—calcium, with oxygen. Slacked lime is called the hydrate of lime, being a combination with water. There are also the sulphuret of calcium, and the nitrate and the phosphate of lime. This last is a principal ingredient in the bone dust manure.

The elements of Gypsum are found in the the ashes of most vegetables, and are therefore necessary in the soil; for example, the crop of turnips mentioned above, removes from the soil 45 lbs. of lime from the acre, and 49 lbs. of sulphuric acid. The red clover 63 lbs. of lime and 10 lbs. of sulphuric acid. The wheat—grain 1½ lbs. of lime and 8-10 of a lb. of sulphuric acid, and the straw 7½ lbs. of lime and 1 lb. of sulphuric acid.

Liebig recommends gypsum to be employed for fixing the volatile ammonia of the manure yard, which produces a sulphate of ammonia and carbonate of lime. The use of salt, as already mentioned, seems preferable.

WHEAT BRAN.—We have not at hand an exact analysis of this substance—but from the analogy of other vegetable manures in a dry state, we should say its value would be greatly enhanced, by promoting its fermentation, by mixing it with the liquid manure of the farm yard. In this case it could not fail to afford a valuable addition to fertilizing matter.

WOOD ASHES are different according to the kinds of wood from which they are derived.—The hard woods generally afford carbonate of potash and silicate of potash, both valuable either in feeding plants directly or in reducing other matters into a form fit for food to plants.

In the crops already referred to, the turnips carry off from the soil 145 lbs. of potash, red clover 45 lbs., wheat grain 3½ lbs., straw ½ lb. per acre.

LEACHED ASHES differ from the above, merely by the removal of the greater part of the potash.

ROTTEN WOOD contains the same elements as the tree from which it is derived, except that a portion of its carbon has combined with the oxygen of the atmosphere and passed off as carbonic acid gas. The elements of potash, &c., are in a condition to be more immediately available for nourishment than in saw dust.

SWAMP MUCK.—This substance consists of different materials in different cases—but generally, it consists of vegetable matter in a very inert state. On burning, it will be found to give off organic elements similar to living vegetables, and the ashes will show similar saline and earthy materials. Lord Meadowbank, as re-

ported by James F. W. Johnson, made many important experiments on this substance, especially when it takes the form of peat, the result of which is, that it may be rendered active, by being partially dried in the air and mixed in a compost heap with about half its weight of hot fermenting animal manure, or even by exposing it to the vapors which rise from the naturally fermenting farm-yard manure. If it can be made to ferment in any way, it is thereby converted into a rich fertilizing substance. Johnson is of opinion that the dried and pulverized peat, with a small mixture of animal matter frequently wetted by pumping over it, from a proper cistern, the liquid manure, would soon undergo this needful change.

Lime.—The analysis of this substance has been given already. Its value in agriculture has been long known. It pulverizes stiff clays; it hastens the decomposition of vegetable matter, either in the soil or in the compost heap. By this decomposition carbonic acid and other compound substances are produced, which serve for the food of plants. In the crop already referred to of 25 tons of turneps from an acre of land, there are removed from the soil 45 lbs. of lime; in a ton of red clover 63 lbs.; and in 25 bushels of wheat grain 1½, straw 7 lbs.

Hen Manure, (with that of pigeons and fowls generally,) contains a good proportion of nitrogen, an element always valuable as food for vegetation. In Flanders, the produce of 100 pigeons is worth 20s. sterling per annum, for agricultural purposes.

"The Guano, or Huano, has recently attracted great attention; no less than 40,000 tons having been shipped to England as a manure.—Much discussion has arisen as to its nature, but the received opinion at present is that it is bird's dung. It is found on the islands adjacent to the coast of Peru in such enormous quantities as to induce much skepticism as to its origin. In some places it lies from 80 to 100 feet in depth; feathers and egg shells are frequently found deeply buried in it; it was used as a manure by the Indians long before the conquest, and without it, the valleys of Peru would be almost desolate; it is pungent in the extreme, and, if used in large quantities, burns and destroys vegetation, while in smaller quantities it vivifies and gives extraordinary rapidity to growth."

The following is an analysis of two specimens of Guano, showing very different results:—

1. Water, salts of ammonia and organic matter expelled by a red heat	23.5 per cent.
Sulphate of soda	1.8
Common salt and a little phosphate of soda	30.3
Phosphate of lime, with a little phosphatcof magnesia and carbonate of lime	44.4
	100
2. Ammonia	7.0
Uric acid	0.8
Water, carbonic and oxalic acids	51.5
Common salt, with a little phosphate and sulphate of soda	11.5
Phosphate of lime	29.3
	100

We regret that we have not at hand an exact analysis of the other animal manures mentioned. In general, it may be stated, that their value is in proportion to the nitrogen they contain, and in this respect they stand in the following order:—64 lbs. of the mixed, solid and liquid excrements of the hog are equal to 36 ditto of the sheep, 54 of the horse and 98 of the cow—to the solid of the horse 73; do. of the cow 125—to the liquid of the horse 16; of the cow 91; to pigeon's manure 5; dry woolen rags 2½.

Ink.—You may restore ink that has been frozen, by dropping a small lump of gum arabic into the ink bottle, and when it dissolves, shake the ink well, and the gum will hold the coloring matter in solution.—*Alb. Cultivator.*

AGRICULTURAL EDUCATION.

The following extract, says the Farmers' Gazette, is from the address of the Hon. S. H. Huntington, delivered before the Hartford county Agricultural Society, at their last annual exhibition. Mr. Huntington is a practical farmer, and was last spring appointed Judge of the County Court, by the Legislature, and we find him an excellent judge as well as a good farmer. The counsel of such men are well worthy of attention.

"The farmer's standard of education is too low, but not especially so, in reference to his own occupation. He is a co-worker with Providence in the laboratory of nature; and yet how little does he really understand of the materials he operates upon; the nature of his various soils—the power and adaptation of his manures—the singularly curious combinations he forms, and of the beautiful and almost miraculous operation which he puts in motion, to produce the crowning fruits of his efforts. Not so with all other pursuits; the mechanic perfectly comprehends the principle upon which he combines. Science has arranged and reduced to system his art, and he is considered as but half accomplished in his trade, if he can boast of nothing beyond a skilful use of his tools. So with all other professions; knowledge is the most extensive and varied, where the science is of daily, nay, hourly application, in the construction and use of our numerous implements:—where animal and vegetable philosophy invite us to their investigation, as a matter of interest, as well as attract us by disclosing the beauties and wonders of creation—where chemistry is absolutely required to enlighten and guide us in the composition of the materials of fertility—and where geology should point out to us the origin, and explain the nature and adaptation of our soils, it is too generally considered that the very lowest grade of our common school education is most abundantly sufficient. How often do we see among the sons of farmers, one destined to a learned profession, and another, perhaps, to commercial life. The first is eventually found at some one of our colleges, and the other is, year after year, at the high school or academy; while to him who is destined to succeed his father on the farm, two or three winters at the district school, after he has entered his teens, is about all that can be afforded. Thus, while schools and colleges are established, patronised and endowed from taxes paid by the farmer, for the education of those employed in other pursuits of minor importance, agriculture has not, as yet, found the first professorship endowed for her advancement.

"The consequence of all this has been to degrade the position of the farmer; to render a pursuit, of all others the most interesting, and, in itself, the most attractive, repulsive to our young men of enterprise and intelligence, to lead them to look upon the labors of the husbandman with contempt, as though they were disgraceful.

"But the effect upon the farmer in reference to himself, personally, is still more lamentable: it too often and to effectually closes the avenues to the mind against all improvement. The rule of doing as their fathers did, is to be adhered to at all events, for it is honoring their memory. A labor-saving implement is rejected as an innovation, and to assail a system of cultivation which has received the sanction of half a century or more, notwithstanding the effect may have been to render the lands almost worthless, is presumption—absolute madness. All real improvement, therefore, connected with the cultivation of the soil, is received with far greater reluctance and extends with much less rapidity among the farmers than among any other classes of men. It is said that the late Mr. Coke, the most distinguished agriculturist of England, could trace the progress of his own improvements upon the adjoining lands of his neighbors, as distinctly as he could trace their boundaries; attempts at persuasion effected nothing, and while he exhibited an almost miraculous renovating of a comparatively barren soil, many years passed away without the extension of his improvements half as many miles. What, let me ask, is the remedy for this great evil?—and would that I had energy to send home the inquiry with resistless power, to every farmer of our land. It is education—intellectual improvement—the expansion of the mind.

"The culture of the mass of mind should be deeper and more thorough, and then it will act as one of the most sufficient means of a deep and thorough cultivation of the soil.

"Position, as a class, would thus be greatly elevated, for, happily as yet, in our country education, under all circumstances but those of abuse, commands deference. Physical labor would be rendered more respectable, and we should assume that relative position and influence to which our numbers so justly entitle us. Then, our young men, as they seek to rise in life, would not consider it as a matter of course, that they must escape from the farm—but would be induced to pursue agriculture, not only as a source of a reasonable competence, but as the path to influence and distinction. Society would become generally refined, and that great evil, (fondness for the tainted atmosphere of a large town,) would give place to a pure and primitive love of rural life."

MANURES.

It becomes us in this enlightened age to look to our ways, and if there is any method which tends to improve or augment the productions of any branch of industry, most surely should it be received and practiced. It has been, and still is, a matter of regret that the farmer should be so backward to receive the truths which science and close observance have brought to light; but if appearances are not deceitful, that backwardness is slowly being removed. Well has it been said, that "manures are the farmer's riches."—But how little pains are taken to husband those riches; no one can reasonably expect a succession of good crops without them.

If manures are so necessary for good husbandry, why is it that they are so much neglected and allowed to waste? It may be considered a broad assertion, but it is none the less true, that not one in a thousand in the State of New York, properly saves those manures in common use, namely, the solid excrements of animals.

But it has been shown by experiment that liquid manures, which are every where allowed to waste, are equally beneficial when applied to plants. The Chinese apply liquid manures almost entirely to vegetation, and in no country has agriculture reached that degree of perfection as there; scarce a weed is to be found on the land, and in their fields of grain, naught but grain is seen; which is, in a great measure, owing to the fact that they do not carry on to the land, in long or barn yard manure, an immense reservoir of the seeds of grain, noxious plants, &c. Liquid manures, it has been proved by direct analysis, to contain in large quantities, those ingredients which are not only highly nutritious and stimulant, but in the state to be most easily absorbed by plants.

It would be but little expense for the farmer to prepare his stables so as to collect this kind of manure, and convey it to a large reservoir, so covered as to prevent evaporation, and there saturate it with earth, or apply it to vegetables in the liquid state. It is considered best for grass lands, and to such it may be applied, if liquid, by placing a large hogshead or some other vessel, on a cart, fill it by means of a pump, then cause it to flow into a box four or five feet in length, the bottom pierced with holes, then by drawing over the ground, it is distributed evenly and with little trouble. A cow, in five months, discharges urine sufficient as manure for half an acre, of the richest quality and of the most durable kind. The excrements of a healthy man, solid and liquid, are sufficient in one year to

nourish the most exhausting crop on one acre of ground, and yet neither of these manures are applied to the soil—save what little of the former may be absorbed by the litter of the barnyard. The most convenient method of securing the liquids of the barn yard, is by causing the yard to descend towards the centre, and absorb them with straw or other litter, a means of which most are acquainted. I would not neglect the solid manures, to preserve those that are liquid, but both can be saved and both should be. If all the manures which are in the power of every farmer, were properly husbanded and applied to the soil, one great step would be taken to advance the agricultural intе ests of this country—farmers would reap better crops, and that portion of our country which has been "worn out," might again be made to yield plentiful harvests.

The agricultural community, as a mass do not take sufficient interest in improving the mind, and as long as the most essential part is left uncultivated, the science of agriculture will not move on with rapid strides towards perfection; neither will they apply the principles which have been brought to scientific men, in such a manner as to be beneficial, though if rightly understood by men who had studied and seen the beauty of them, would greatly advance this valuable science. Every farmer can at least do this, take at least one paper devoted to his interests, and form a little library of agricultural books, to read at liesure hours; he can procure some choice volumes on this subject, and will therein find many valuable hints, doubly worth the price they cost.—*Central N. Y. Farmer.*

PREPARATION OF SEED WHEAT TO PREVENT SMUT.

As the season for the active operations of the farmer is now approaching, it is important that any hint that may be made serviceable in the production of our staple crops, should be placed before the community in time to be made use of, if it is worthy of imitation. For this reason I send you a note of my practice in preparing the seed of spring wheat, to prevent smut; I have not tested it on winter wheat, but I think it would be decidedly beneficial.

For the last five years, I have been in the habit of preparing my seed in the following manner: In the first place I make a brine of common salt, as strong as it can be made by beating and stiring, in this way it can be made so strong that it will raise all the oats and imperfect grain. When the wheat is made perfectly clean, and separated from the brine, I mix slacked lime as long as it will stick to the wheat, and sow it immediately, if I am ready, but I have let it stand twenty-four hours before sowing, without injury to the wheat; I should think it prudent however, to sow it, for a general rule, within twelve hours. Since I have been in the practice of treating seed in this manner, I have not been able, on any occasion, to detect a particle of smut in my wheat. When I consider, that in particular instances it has been detected in wheat, where the seed was not prepared with brine and lime, and also in the case of my neighbors who have neglected it, and have generally had more or less smut, I can feel no hesitation in stating my belief, that the treatment of the seed has been the cause of preventing smut. I am aware that we have multitudes of experiments, given by able and most excellent farmers, to test the cause and prevention of smut, and what is very strange, every writer seems to have found out a new cause and means of prevention.

I am very confident that many causes may produce smut, such as imperfect seed, and perhaps the effects of too wet or dry seasons, acting with reference to a peculiar condition of the soil, and all, I believe, agree that smut on the seed, has a strong tendency to produce smut again. I do not pretend to have made any new discovery, but I am certain that I have been benefited by it, and am anxious that others who perhaps have never had their attention called to the subject, may also test its value. Should this article meet the eye of any of our farming friends, who do not believe in "book farming," and who have "always known that," I would respectfully solicit, that they would let down their dignity and self-complacency a little, and for once try a book experiment, and see if they are not benefited, and if they are, will they not try a "book?"—*Central New York Farmer.*

Preparation of Seed Wheat.—By sifting wheat in seives that will retain the large seed only, a selection of the best grain will be made. Wash seed wheat thoroughly in water several times, and skim off all the light seeds, shriveled kernels, oats, &c., that swims on the surface. Then dissolve salt in water, as much salt as the water will take up, soak the grain in this brine. This will cause other berries to float, and some oats that may remain, which may be removed. Let the grain remain in the brine half a day, or a night, and longer if you please, if the water be fully saturated with salt, and the grain be kept in a cool place. Wheat has been kept in this manner, in good condition, two or three weeks, in cases of storm which prevented sowing it in season.

After soaking in brine, lime the train with fresh slaked lime, mixing and stirring the grain and lime well together, so that every berry may be watered with lime. Let it remain half a day or a day before sowing. This method has been well tried thousands of times, and almost invariably it has proved a preventive of smut. It is a very cheap preparation, and besides guarding against injury from smut, it will serve as a protection, in some measure, against insects, as they dislike lime and salt. These substances, as far as they are used, are useful as a manure.

Boston Cultivator.

Prevention of Smut.—Putche's (German) Encyclopedia of Agriculture gives the following as the celebrated recipe of Mons. Sckruitz, of Duerer, in the province of Juliers, (Prussia) for preparing seed wheat so as to prevent smut in the crop. So confident was Mr. S. in the efficacy of his method, that he offered a standing reward of a ducat for every head of smutted wheat found in his fields.

For every 500 lbs. seed wheat take one lb. of allum, one lb. copperas, ½ lb. saltpetre, ½ lb. verdigris. Pulverise these ingredients and dissolve them in a sufficient quantity of boiling water. When the solution has become cold add as much more water as will be required to moisten the whole thoroughly. The heap should then be turned several times within the ensuing twenty four hours, and well mixed; and it is ready for seeding.

Industry.—Demosthenes, when asked the first requisite to eloquence replied, "action"—when asked the second, he replied, "action"—and the third, he still replied, "action." Industry bears the same relation to agriculture, that action did to eloquence in the estimation of the Athenian orator. With industry the farmer may accomplish every thing, and without it he can do nothing. Let him then study the value of time.

Time is his great capital and should be well invested. The wealth of the world, its high civilization, and all its magnificent improvements, have been created and fashioned by the labor and industry of man. The poorest soil and most unfavorable climate are scarce impediments to an industrious and energetic people. Look at Holland, reclaimed from the ocean, fenced in by her embankments and mud walls, literally a smiling garden, where once there was nothing but bogs and ocean's wave. Look at Switzerland, where an industrious and hardy peasantry contending against the avalanches of snow and ice and emboulment of mountain masses of rock, falling and crushing for miles square every thing before them, have cut the hills and mountain in terraces and planted them with vines.—Lands which before were worse than nothing, by this improvement sell for ten thousand francs per acre.

CURE FOR INFLAMED EYES OF THE HORSE.

Notwithstanding my occupation requires my attention and exertions in attempting to cure or palliate the "ills that flesh is heir to" in the human species, my sympathies have been occasionally enlisted in behalf of that noble animal upon which we are so much dependant for many of our pleasures and comforts, and derive so much important service—the horse, in consequence of the empyric and barbarous treatment frequently practised upon him.

If the animal who claims for himself the image of his maker, is willing to indulge in Brandreth's Pills, Lobelia, Magnetic Ether, and Jew David's Plaster, and write for his epitaph, "I was well, took physic and died," let his curiosity be gratified; but while we assume to ourselves the guardianship of the fourfooted part of creation, let us discharge the duty in that manner that shall at least entitle us to the virtue of humanity.

Not unfrequently when I have been giving my horses high feed and severe service in hot weather, over hard and dusty roads, I have observed them frightened and shy from objects to which they usually paid little or no attention; and upon examination of the eyes, have discovered the external membrane (*tunica conjunctiva*) thickened so much as to impair or obstruct the vision, presenting a whitish appearance occasionally in spots, but frequently involving the entire membrane covering the organ. At this discovery many kind friends, actuated by the best of motives, would volunteer their aid and advice, for the purpose of removing the difficulty. Mr. A., exhibiting an air of great confidence in his skill in such matters, would say: "You must pound glass until it is very fine, and blow it into the eye through a quill, to *cut the scum.*" A remedy, or rather an intended remedy, that would most assuredly render him blind, even though the disease should fail to accomplish that result. Then comes Mr. B.: "Sir, you must blow burnt alum in that eye." Mr. C., quite as knowing as his neighbors in these affairs, makes the following prescription: "Blow powdered blue stone into it, and rub a little rabbit's grease above the eye, and my word for it, to-morrow morning it will be as bright as a diamond.

By just such treatment many a noble roadster has been prematurely consigned to the cart or tread-mill; whereas, had the matter been intrusted solely to the operations of Dame Nature, the result would have been widely different.

The course that I invariably pursue in such instances, is to keep the animal in a dark stable, to be fed upon hay, or if practicable, fresh cut grass and coarse bran—bleed freely from the mouth, and administer one and a half pounds of Glauber salts, two drams of nitre, and fifteen grains of tartarized antimony in a bucket of water, and repeat the same daily until free purgative operation is produced. The animal will be invariably found in a feverish condition, and if kept from water for a short time will drink the mixture freely. If these means do not soon produce a salutary impression, I bleed from the large vein immediately below the eye. By placing the thumb of the left hand firmly upon the part, the vessel soon becomes distended, and the operation may be most conveniently performed with a common spring lancet. By this means I have frequently succeeded in extracting from 12 to 20 ounces of blood, which has acted like a charm, by relieving the engorged vessels of the inflamed membrane. The whitish or sometimes yellowish appearance, depends upon the effusion of coagulated lymph deposited during the acute stage of the disease. When the absorption of this does not progress freely, and the eye fails to assume its accustomed lustre and transparency, I blister a semicircle below the eye, one and a half inches in diameter, by applying daily with the point of the finger, a mixture of three parts of the common blistering preparation as obtained from the druggists, and one part Venice turpentine. Sometimes the other membranes of the organ become diseased from similar causes, to remedy which, the foregoing treatment as de-

tailed will be applicable. Care should be observed in not too suddenly exposing the patient to a strong light, high food, or active service.

Thus I have given you, as our Buckeyes term the science, a chapter on "horse-doctoring," and if you perceive anything in it that will repay you for the trouble, you are at liberty to publish it, with the promise, if it meets your approbation, of resuming the subject in some future number. ANDREW CAMPBELL, M. D.

Middletown, Ohio, February, 1843.

American Agriculturist.

BLIGHT IN PEAR TREES.

In the August No. of Vol. I., of the American Agriculturist, I find a notice of the blight in pear trees. I will give you my observations on that subject the past summer, and although very imperfect, they may throw some light on a subject that is enveloped in mystery, notwithstanding all the numerous causes and preventives that have been published. On the 23d of May last, I was observing a pear tree, some of the branches of which were dead, others with the leaves turning brown, the fruit dropping off, and what is peculiar to this disease, the branches in another part of the tree appeared perfectly healthy and vegetation in full vigor. I commenced paring off the bark on the diseased branches, which presented quite a red appearance, and in places a reddish liquid was exuding through the bark. In these spots (after taking off the outer bark) there was a very small hole about the size of a number 10 sewing-needle, and on removing the inside bark to the wood, there the little destroyer was ensconced, feeding on the life of the tree, to which they must be a deadly poison. They were near, and in the body, and for several feet up and down, the bark and wood were stained as above. I shaved the bark all clean where the tree was affected, which was on one side from the roots to the branches. I found only six of the insects; they are inactive, about the size of the hole mentioned, and above the sixteenth of an inch in length. They have six legs, the sides a deep green, the rest part of a brownish color. They insert about half the length of their body in the wood. I was pretty well convinced at the time, that these insects were the cause of the disease, but they may simply be the effect of it. They do not appear to be a migratory insect, for there were other pear trees standing within fifty feet of this one, unaffected two years ago. The tree which stood near this one died branch after branch, until the top was all cut away. Now this is one stage of the insect; and if we can find out its habits, there will be some chance for a remedy.

Professor Main, in his excellent treatise on the Physiology of Plants, mentions this disease, called American blight, and states the cause to be a very small insect, which, in its early stages, is not discernible with the naked eye. He calls it the *coccus*, or *Mealy aphis*, or a species of the *Cochineal* fly of commerce. The effect produced coincides with my observations; but the insect as I saw it differs in color from the one he describes as doing the mischief. He says they are so light that they are easily wafted from tree to tree, which can not be the case with this one I speak of. Apple trees are subject to a similar disease, and I have discovered the red juice, and the red appearance of the bark and wood, but not the insects.

There is another insect that works upon the pear tree, giving it the appearance of blight, but it is not the cause of the destruction of our pear trees. The fly deposites its egg in the tender part of the end of the twigs, and hatches into a brown grub. When full grown, it is about an inch in length. It eats out the wood, and leaves the bark entire for its habitation; of course the twig dies, the leaves turn brown, which gives it much the appearance of blight. I have cut off these twigs and found that they were hollow for six or eight inches. I can tell you nothing about the habits of this insect.

—

TO DESTROY BUGS ON POTATO VINES.—An old gentleman informs me he has completely mastered the potato bug, by boiling up the roots of the mullen, and sprinkling the liquor on the tops early in the morning. He says it has the same effect on tomato vines.

—

REMEDY FOR SORE TEATS AND INFLAMED UDDERS.—White lead and sweet oil are excellent for cracked or sore teats of milch cows.

Flax seed oil, well rubbed on the udder when inflamed and cracked, will allay inflammation and soften the hardness of the bag. Rub well twice a day until the inflammation subsides.

With much respect,

E. CARPENTER.

American Agriculturist.

CURIOUS METHOD OF PLANTING CORN.

Mr. John W. Sweet, of Tyringham, Berkshire county, informs us that he plants his corn in the following manner, and has realized 110 bushels shell corn to the acre.

He spreads what manure he intends for the field on the surface of the green-sward; then he plows the land into ridges about three feet apart in the fall—each ridge or row being made of two back furrows turned upon a narrow strip of sward which is not disturbed. In the spring he rolls and harrows these ridges, and on the top of each ridge, 12 or 14 inches apart, he plants his hills of corn, three or four kernels in the hill, and cultivates the corn through the season with the hoe, cultivator and plow, as much as he deems necessary. In this method, he remarked that he was not troubled with weeds or the drought.

In the fall, as soon as his corn is ripe, he gathers the ears, then pulls up all the corn stalks and lays them down lengthways between the furrows, and then splits the ridges with his plow, and covers these stalks up completely. Thus is made his ridge for his second crop of corn, to be planted the succeeding spring. The 110 bushels was the second crop planted over the buried stalks.

The above is sufficient to give the reader an idea of this system. He contends after the first crop he wants no more manure for his corn except the stalks applied as we have described.

It is quite probable, the three sods and manure being under the corn the first year, that while these are undergoing decomposition, being the whole period of the growth of the corn, the crop will suffer less from drought than it would were there no vegetable matter beneath it to attract and detain moisture till its decomposition is completed.

As to the fact that cornstalks are the best manure for corn, the idea is strictly philosophical, and is fully sustained by chemical analysis.—The doctrine seems to be well settled, that each crop requires its own peculiar food, and unless the soil contains this, the crop will not flourish. Hence the necessity of rotation of crops, or the well established fact, with practical men, that potatoes will not thrive for many years in succession on the same piece, because the crop has already exhausted the soil of the peculiar food of the potato, while some other crop requiring a different kind of food from what the potato requires, will succeed well on the same land where the potato crop has failed. Thus as the ox and the sheep, when put to the same stack of hay, the one will eat what the other leaves; so it is with plants.

Now, if you shoot a partridge, and cut open its crop, and find in it acorns and buds, you at once infer that acorns and buds are the natural food of the bird. So when by chemical analysis you ascertain the precise elements of which corn stalks are made, you have ascertained precisely what kind of food the corn crop requires. Now as corn stalks contain the very elements of the food required by the corn crop, and return to the soil all the substances of which they exhaust the soil, the chemistry of agriculture teaches us that corn stalks, while undergoing decomposition, furnish the growing crop with those very gases required for the elaboration of the solid stock and ears.

But this is not only the conclusion of science, but a universal law of the vegetable world, by which an all wise and bountiful God has provided that each precise species of plants shall be reproduced and perpetuated. Thus the forest land, for centuries subject to a mighty growth, from year to year, not only increases in fertility, by an annual top-dressing, fitted to the very purpose for which it is wanted, and composted by the unerring hand of Deity, but also, from year to year, has something to spare for the good of man and beast.

Thus in the vegetable as in the animal world, there is a wise provision, that each shall be sustained and reproduced; and as these natural laws are more and more developed by science, we may expect the purposes of Infinite Wisdom, as to the vegetable world, will be less and less frustrated by the hand of unskilful culture.

Boston Traveler.

MANAGEMENT OF BEES IN THE SPRING.—If the hives are kept in the shade, and where it is rather dark, bees will not attempt to go out till they can do it with safety; but if the sun shines on the hive, it makes a milder climate in and around the hive, than there is out in the fresh and chilling breeze, and the bees will be induced to go out when it is too cold, and becoming chilled they fall on the snow or cold ground and die by thousands; and by these revivals they will be more in action and consume more honey

In the spring, when warm weather commences, or just before, if any one can guess aright in such a season as this, take out the board on which the hive sets, scrape off all the dead bees &c. and wash it thoroughly. Then let it dry and wash it over with a whitewash of lime with a good lot of salt in it, even more than will dissolve. Whitewash also the lower edge of the hive, and up in the hive to the comb. The whitewash is very acceptable to the bees and they will eat it freely.—*Boston Cultivator.*

MANURE.—Put on your land all the manure that can be scraped from your premises, or that you are entitled to from the road. Leave not a particle in the barn yard. It matters not how coarse or long it is, if you can plough it in. All you get from it before another season is clear gain, for it will lose but little more under the ground with a crop over it, than exposed to the action of the sun and rains in the yard. If it cannot be used, place it in heaps and cover it two feet thick with earth, which will inhale and retain most of its enriching gasses till wanted.—*American Agriculturist.*

VINEGAR.—Get a good cask and put in into your cellar. Procure a gallon of good vinegar, and let it stand in your cask a day or two, occasionally shaking it around the cask. You may then commence filling up your cask gradually with whiskey and water, in the proportion of one gallon of the former to eight of the latter.—It is best not to fill it up too fast at first. By this process you may always keep an abundant supply of the purest vinegar.—*Alb. Cult.*

☞ In an experiment of sowing corn *broadcast*, on the 1st of June, at the rate of one and a half bushels per acre, on rich land, Gen. Harmond, of Wheatland, Monroe county, New York, obtained 18 tons of green stalks per acre. The stalks were small, and almost entirely without ears, and so full of saccharine matter, that the cattle ate them perfectly clean when dry, though they were not cut up fine. The yield was estimated at six tons dry fodder per acre, was raised on a clover sod turned over and sown the last of May, and the corn cut September 15. The saccharine matter, which goes to supply the corn in the ear, is retained in the stalk when not suffered to ear, and materially adds to its nutritive properties.—*Am. Agriculturist.*

"In matters of business, if you can help it, as far as possible never commit yourself by speaking first; and on no account commit yourself by speaking hastily."

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

DO YOUR WORK WELL.

With whatever justice this remark may be applied to all the vocations of men, there is certainly no pursuit to which it applies with greater force than to that of agriculture. Upon its strict observance success in every department of business depends, and it is, therefore, a maxim of great importance to all classes of business men, and particularly to farmers, because of the almost certain reward it brings to labor. We cannot, therefore, at this time, when all are industriously engaged in the labors necessary to the rearing of another crop, impress it too earnestly upon the consideration of the planter. It makes an appeal not only to his interest, because of the increased production of his farm which it brings, but it promises a rich reward in the happiness and comfort and ease with which it encircles the family group;—for wherever there is a consciousness of having discharged well and faithfully whatever duty our business may have imposed upon us, there is much food for high and unalloyed enjoyment; and no man enjoys more the felicity of such a conscientious discharge of duty than the farmer. The fruits of his labors are ever present to him, wherever he turns his eye upon his farm, and in proportion as he has executed well his work, does it delight him to review the fields which are ever teeming with the rich rewards they yield to his industry. Upon this subject the "Central New York Farmer" says, with much truth:—"Whatever system may be adopted, we cannot too strongly urge upon our farmers the propriety of doing their work well, and of cultivating their fields in a perfect and thorough manner. It is to be feared that the hard times will operate injuriously to agriculture, by preventing improvements which would be undertaken in more prosperous times. Every farmer must decide for himself how far his means will permit him to go; but we must be allowed to suggest that if the labor or expenses on the farm are to be curtailed, it is far better to let some fields remain uncultivated, than to undertake to cultivate much land with little labor. Here lies the secret of success in farming—for every man who has ever tried both methods, must be satisfied that it is better to cultivate a little land well, than a great deal imperfectly."

Industry and economy constitute the wealth of a nation.

MANURING—ITS VALUE.

The annexed communication of Mr. L. F. ALLEN, which we find in the American Agriculturist for April, establishes so fully how much may be accomplished in the resuscitation of exhausted lands by the application of manure, that we deem it peculiarly appropriate for the consideration of Southern planters, and therefore commend it to their consideration. In all the older settled parts of the Southern Atlantic States, the eye of the traveller is met at every step with thousands of acres of land, which, exhausted by our system of culture, are now not only unproductive, but a mere waste. That these lands, or a great portion of them, may be reclaimed by an enlightened system of culture, we have never entertained a doubt. To accomplish a result so desirable, however, resort must be had to manuring, without which we shall go on exhausting the lands, until our whole country will be little better than a barren waste, and our population seeking a better reward for labor in more fresh and fertile lands. Our whole system is wrong, radically wrong; the greatest evil of which is the persevering efforts of every farmer to cultivate too much land—so much, indeed, that they are unable to bestow that attention to the improvement of their lands, so necessary to increased production. This evil must and should be corrected, and planters should learn that it is much better to cultivate fewer acres well, which are all the time improving in value and increased production, than to cultivate much and have it exhausted yearly, and consequently yielding a poorer reward for labor.

A MARYLAND FARM.

AGRICULTURAL CAPITAL.—I have frequently, in reading over the foreign agricultural journals, been astonished at the lavish expenditure of capital on the landed estates in England, to promote their fertility, reclaim them from waste, or bring hitherto worthless tracts under cultivation, wall them in from the sea, and otherwise render them more productive; but on further examination my wonder has ceased, when I learn that in almost all cases of such improvement, the capital thus expended has produced a liberal additional interest on its investment. Probably no department of British industry receives so liberal an outlay of capital as that of its agriculture, affording in this particular a marked contrast to our American agriculture, which scarcely anywhere receives, and even then grudgingly, but an investment of moneyed capital sufficient to render our lands habitable, by a large proprietor. How often do we see proprietors with large landed estates lying in a ruinous, dilapidated condition, with but a few meager acres carelessly cultivated, around their dwellings, which last appendage may be even elegant and costly, while they have their tens of thousands invested in some bank or insurance company, or in bonds and mortgages, which, if withdrawn, and intelligently invested in the improvement of their estates, what noble revenues, as well as delightful employments would result from it, instead, as is often the case, of wasted fortunes from the insolvency of their debtors, and of personal ruin to many a worthy, and, under different circumstances, promising young man, resulting from idleness and dissipation, arising simply from want of employment!

Yet, with all our experience in these matters, hardly an individual can, at this time, make an investment of capital in agriculture, but, ten to one, he will be looked at with suspicion by his monied friends and associates, and either his judgment or his credit, according to his expenditure, is an once suspected. This we know to be all wrong, and the result of a perverted and false estimate of the true value of agriculture, and its safety and sure reliance for support, in all times and seasons, and the steady virtue and integrity of those who rely upon its bounties. How many, and many young men have I known, sons of rich, pains-taking fathers, who, indulged in habits of ease or of loose attention to business when boys, yet with sanguine expectations hereafter, on attaining their majority have been placed in business with a handsome capital, and in two, three or five years, as the case may be, had lost every farthing, and thousands besides, the property of others, who had confidingly trusted to their good management! Yet if these fond fathers had invested the same sums in good farms or plantations, and given their sons a plain agricultural education, ten to one they would have proved prudent, useful, thriving citizens, and good contented, and happy farmers, instead of, at an early age, broken down, disappointed and unhappy men. And all this from a false, imperfect estimate of the agricultural profession and its dignified and sturdy resources.

A MARYLAND FARM.—But to the main subject of my letter, instead of a homily on false principles and habits. In a brief journey to the seat of government, last June, when arrived at Baltimore, I made a diversion from my route, to visit a gentleman located near the Ohio railroad, about thirty miles west of the city, and to view his fine estate, and see his herd of beautiful Devon cattle, for the care of which he has long been celebrated. I found him on his farm of some seventeen or eighteen hundred acres of fine rolling land, a garden amidst a poorly cultivated yet pleasant country, years ago worn down by hard cropping of corn, wheat and tobacco, but of good natural soil and capabilities. Here, retired upon his estate, with a plain but beautifully situated dwelling and out buildings, and all the necessary appliances for a gentleman of wealth, education and leisure, he has for many years lived and improved his estate, until it has become one of the most valuable in the country; and from a condition which, when he first began its cultivation, was sterile, worn out and almost worthless. I spent a day in rambling with him over his fine domain, and never have I been more pleased and instructed. As this is a full and successful illustration of what may be done in almost all our Atlantic States, in the improvement of worn down soils, I trust I shall be excused for giving it somewhat in detail. When the proprietor first located on his farm it was entirely unproductive; yielding no crops, giving no manures, and possessing no resources of fertility, other than the muck or swamp-holes, occasionally interspersed among the woods and waste lands of the estate. After thoroughly examining the soil, which was found to be of various kinds, but chiefly a loose friable earth, based on a clay bottom, with occasionally tracts of stiff clay on the surface, he purchased a limestone quarry a dozen miles distance on the rail road, erected two large kilns at the depot near his estate, and went vigorously to work in getting out the stone, roading it to his kilns and burning it. This material, delivered on the farm, costs on an average twenty cents a bushel. The bushes and straggling woods were cut and made into fuel, the fields were squared out and put into shape, and the quick lime applied at once upon the land, in quantities of from fifty to two hundred bushels to the acre, no matter at what season of the year. When the lime was ready it was applied, by dropping it in heaps of five or six bushels each, and, as soon as sufficiently slaked by the weather, carefully spread on the soil. A great part of the land was so sterile that it had no sod upon it, and was sadly disfigured with gulleys made by the washing of the rains. In such fields as had a tolerable sod of grass, a slight dressing of barn or stable manure was obtained and applied with the lime, which being ploughed became at once productive; but where no manure was placed in aid of the lime, it was left untouched to dissolve with

the rains and snow, and incorporate as best it might with the soil. Under this latter process the soil became gradually grassed over, and in two to four years, a fine coat of native blue grass (*poa pratensis,*) and white clover, (*trifolium repens,*) affording beautiful succulent pasture, covered the ground. When this grass coating is accomplished, the land is in proper condition for cropping, and, with a thorough ploughing, yields abundantly of all the grains and grasses grown in this climate. Where there is no vegetable matter in the soil for the lime to act upon, I conceive the lime must have drawn most of the fertilizing matter from the air, condensing the ammonia therein contained, which is brought to it by the snows and rains. Of course all that is thus procured, is so much added to one's wealth by a very moderate outlay. It also seems to predispose the materials of the soil to form those associations and tendencies which enable it to produce vegetation when in no condition to do so before.

In ranging over the estate, we examined particularly the land, from fields limed years ago, and in the fulness of their production, to those yet white with its recent application, and just looking green with the fresh verdue of the young grass. One field contained fifty acres of the most beautiful wheat I ever saw, promising to yield full forty bushels to the acre. Another, of seventy acres, was newly planted in Indian corn, and had a fine chocolate-colored soil, which had produced its sixty and seventy bushels per acre. The oat fields looked rank and fresh, and the grass lots for hay were, many of them, thus early, lodging with the over-growth of their burdens. Such timothy and clover, and such orchard grass meadows, are rare in that region. In short, by the application of lime in this manner, or without the aid of stable manures, all the cultivated lands were teeming with fertility and abundance. Hundreds of acres thus limed for years, now in beautiful pastures, had been untouched by the plough, and were grazed by herds of cattle, sheep and horses, rioting in its luxuriance. Eleven hundred acres had thus been limed, and new fields were waiting for this fertilizing stimulant, still in the process of application. I saw large tracts of land so sterile that no vegetation grew upon it, not even grass or weeds, separated only by a fence from those bearing the richest herbage. One had been limed—the other not.

I had never seen a specimen of agricultural improvement which had pleased or interested me more than this; and when, in addition to this teeming abundance, all the appliances of rural luxury and independence, buildings, orchards, groves and delightful scenery were added, the picture was full of admiration. Yet all this beauty, fertility and abundance was created by the simple application of scientific principles, with the aid of moneyed capital, to this body of otherwise inert and lifeless soil. The proprietor told me that his friends and neighbors had jeered, ridiculed and blamed him for thus squandering, as they termed it, his money on such worthless experiments; but the result has equalled his warmest anticipations, and he has now the solid pleasure of looking at an estate, which when he took possession of it, was absolutely worthless in its income, and not saleable at $5 the acre, now worth eighty or a hundred. In addition to this improvement of the soil, ten or a dozen miles of durable and substantial post-and-rail fences of chesnut and cedar have been built, separating the farm into large and convenient fields, with commodious lanes and entrances leading from the mansion house and farm-buildings. Ample hay and grain barns are erected in many of the enclosures, for securing the crops and feeding the stock; and altogether this may be termed a *pattern farm* of the highest order.

The question may naturally enough here be asked, how should this remarkable improvement occur in this country, and by one who was not bred a practical farmer? The answer is a simple and easy one: by the application of the right principles to agricultural improvement. This gentleman possessed education, enlarged and intelligent views of agricultural improvement, had travelled extensively abroad, and profited by his foreign observations; and after returning to his native State, instead of slothfully sitting down in idleness and inglorious ease, at once applied himself to the improvement of his property, and in giving an example to his fellow citizens of incalculable value. And yet millions of acres in that fine region, now yielding little or no income, might, by a very moderate outlay of capital, be made equally productive. But more of this hereafter.

CURE FOR PILES AND CATARACT.

Mr. John J. McCaughan, of Mississippi, has communicated to the American Farmer, the following remedies for Piles and Cataract.—The first we have heard recommended on several occasions before, as being a very efficacious remedy; but we apprehend that Mr. McG. has misapprehended the disease generally designated cataract of the eye or confounded it with some other, and we therefore infer that his remedy applies only to those diseases of the eye where some excrescence has grown on the outside of the eye ball.

Cure for the Piles.—Carrying the common buck-eye in the pantaloons' pocket, will cure the piles or any other inflammation about the anus. I cannot give a reason for it, but it is nevertheless certain—try it.

Cure for the Cataract in the Eye.—The root of the weed commonly called the *devil's shoestring*, soaked in water and used as a wash, will cut the film (called cataract) off the eyes of man or beast, more effectually than the surgeon's knife, without pain, risk or apprehension."

COTTON SEED FOR COWS.

The following experiment of giving boiled cotton seed to cows, was communicated to the American Agriculturist, in February last, by Mr. Thomas Affleck, of Mississippi. We hope it will not be forgotten by our planters, who can so readily test its value.

Cotton Seed for Cows.—I am now feeding to my cows, boiled cotton seed, with a little chopped corn added. It gives the butter a rich flavor and fine yellow color, and I may safely say, doubles the quantity. The cotton seed must be *well-cooked* though, which a few minutes boiling will do.

GOOD ADVICE.

The following extract from an address delivered before an Agricultural Society in Maryland, will apply with much force to the meridian of Georgia, where, for a series of years, so much time and money have been consumed by the indulgence of luxurious habits, bringing in their train neither that happiness, ease or quiet, in the pursuit of which all are so eager.

"Fellow farmers, let us then, in these times of pressure and pecuniary embarrassment, get rid of every species of property which is not profitable; get rid of our luxurious habits; abandon the fashionable follies of the day; lay off all unnecessary expenses, and return to the plain, unsophisticated customs of our forefathers. Let industry and economy be your watchword, and let it be practically seen and felt in your household. Work less land, and take better care of what you make. Make an annual investment in the improvement of our farms. Let us give up the fashion of selling nothing that we can consume, but rather let us waste or prodigally consume nothing we can sell. By such radical changes in our course of life, and in our system of farming, that peace and plenty, that contentment and comfort, that ease and happiness which is our birth-right as tillers of the soil, will again revisit our homes, and the bright sun of prosperity will again shine over old Maryland in all its wonted effulgence, and light up with happy smiles the countenances of her independent sons and her beauteous daughters."

WATER MELONS AND CANTELOPES.

In the Farmers' Register, we find the following memoranda for the cultivation of these delicious melons, by a gentleman who, in the 43d degree of north latitude, frequently raises melons to weigh from 30 to 40 lbs. each. Although in our climate the water melon often attains a much greater weight, with much less care and attention, we doubt not if the experiment be made upon the plan suggested by the writer, they would grow much larger than now. The system of pruning adopted by this writer, if practised at all by those who cultivate in this climate, is only to a very limited extent, certainly contributes much to the enlarged size of the melons, and we cannot perceive how it should impair the flavor. We hope, as it is not yet too late in the season, some of our friends will make the experiment with a few hills, and give us the result, comparing its benefits with the culture now generally practised.

Holes, 2 feet diameter, 20 inches deep, filled one foot with garden rubbish and unrotted manures, beat down hard, and watered (two or three buckets full,) then filled to the top with rich soil; on this spread an inch of fine compost or well-rotted manure, compact, but not hard. Stick the seeds, (say twenty or thirty to a hill,) the upper end of the seed to be a little below the surface of the compost; brush over the hill with the hand, so as to fill the holes made by the fingers; then cover the hill with an inch of clear *sand*, often watered. In Alabama, I should think, grass turf, (the grass side down,) would be a good filling for the 12 inches.

Hills, 10 feet apart, 2, 3, and at most 4 plants only to remain in a hill, and standing apart from each other; thinned by the time the plants have six leaves.

If the season be dry, dig down by the side of the hills nearly as deep as the bottom of the holes, and put in a bucket or two of water, filling the hole after the water is absorbed; as soon as the yellow bug is gone, take away the sand and supply its place with soil. This is all that can be done in the hill.

When the plant has six leaves, take off the centre shoot with the point of a sharp pen-knife, and when the lateral shoots are six inches long, take off all but three: when these begin to fall to the ground, secure them down with cross sticks, and as they advance, spade up the ground foot deep in advance of the vines.

Once in every three or four feet put a shovelful of soil on a leaf joint of the vine, (not covering up the leaf,) and press it down gently with the foot on both sides of the leaf; if this is kept moist it will take root. The ends of the vines to be kept on the ground by cross sticks.

Let the vines spread from the hills so as to cover the whole ground.

If the side branches of the main vines are inclined to head up, and not to keep to the ground, take them off, say a foot from the main vine.

All pruning to be done in the middle of the day when the sun shines.

Let no melon set within four or five feet from the root; and then only one on a lateral branch, three to a plant. Let the vine run on as far as it will, keeping it to the ground: permit no melon to grow that is deformed; pull off no male blossoms.

When the melon is nearly to its size, others may be permitted to set on the same vine, and a

second crop raised. I should think the vines might be made to grow from twenty to thirty feet long.

Great care should be taken that the vines are not moved or trod upon.

The *early* but *small* melons. Let the melon set at the 2d or 3d leaf-joint from the root, and take the vine off two joints beyond the melons.

To increase the number of cantelopes. Take off all the melons that set within two feet of the roots.

These may be planted six feet apart, 4 to the hill, and require no particular attention.

Sand on the hills is one of the best preventives against the yellow bug, though not entirely a preventive.

It is useful to plant pumpkin or squash seed near the hills for the bugs, taking care to pull them up as soon as the bugs are gone.

Cantelopes should not be planted nearer than 20 yards to muskmellons or cucumbers.

To improve your seed save none but from the very best melons.

Keep a record if you wish to know certainly the results.

SOMETHING ABOUT HOGOLOGY.

Mr. Editor—As I wanted to send a letter to my old friend Duthan Peabody, who lives somewheres up about Turkey Hills, on the business of Hogology, which is rather a public concern—and as Duthan can read print better than my poor writing, I thought he would like to read a letter to *himself* in your Gazette, knowing that you would put the stops, the spelling, and the grammar all right, I thought I would send it in that way. Then there's the postage on a business letter both ways—some saving in that, you know—hope you will excuse the liberty I've taken.

—

Milford Farms, January 10, 1843.

Friend Duthan—As I am calculating to happen along your way the first good sleighing, and of course shall make you a kind of farmer's call, I thought I would send this as a sort of forerunner, to put you in mind of some notions of mine about farming. You know I am a great lover of hogs, (though not half so hoggish as some of my acquaintance,) and as it's the time among us Yankees to have a slice or two of good broiled ham on the breakfast table when a friend happens in, it occurred to my mind to improve the opportunity to say a few things to you about hogs, and the breeding of them.

And firstly, do you know what's the best, the genteelest, and most fashionable of the whole hog family just now? There seems to be a great many different notions about what it takes to make a good genteel hog, and about the character of the different families—there's great contention about it already. If they only knew what is written, and printed and said about them, they'd prick up their bristles and make war at once. But after all, the hog is the farmer's friend, when he has a genteel, good breeding. But your saucy, ill-bred things are nothing but a torment.

Now, if you want to make a figure in the world, friend Duthan, especially in the farming line, let me, after all my reading and experience on the subject, recommend to your notice the *Berkshires*. I know you, like some other folks, have a sort of antipathy against British hogs, British short horns, and British any thing; (a little of the old Revolutionary feeling I suppose;) but let all that go—the Berkshires are the finest fellows that wear bristles for all that. If you will believe me, it takes a great while to make a genteel, gentlemanly hog like the Berkshires. They are none of your upstarts. It is education makes the man, you know—and so with the hog. By education, I mean, *drawing out* and *improving the faculties* and good qualities.—Why, some of the first and most learned farmers in Old England, lords and noblemen, have been educating the Berkshire family for more than forty years, and their pedigree is as legitimate and canonical as that of the Royal Family—though the original stock was, to be sure, of the Plebian caste, like all the nobility. Mr. Allen of Buffalo, has been on the ground, and traced out their whole rise and improvement, and has given us chapter and verse of all the history for about half a century, of their education, manners, habits and qualities, and can now introduce you to some of the most accomplished and elegant fellows that ever went on four legs.—Why didn't you read what the Committee said about them at the Hartford and Albany Cattle Shows? They made them out the most complete *gentlemen* in their appearance and behavior.

The science of Hogology is so perfectly understood in Old England, that they can educate them by good breeding, into any form, size, color and disposition they choose. They have, as Mr. Allen says, given the Berkshires more good points than any of the Swinish family. They have educated off, already, most all their hair and bristles, two-thirds of their skin, and about half their bones *out*. They have given them size, great r than an Alderman or Lord Mayor of London, "symmetrical, fine-formed limbs, fine, thin, glossy hair, soft lady-like skins, and great hardiness of constitution. Made them prolific breeders, best of nurses, of thrifty growth, early maturity, easily kept on grass, will fatten at any age, their dispositions are quiet, powers of endurance great, and beat all nature to travel, especially when going to Fairs. And besides and above all, their meat is of the *best kind*, lean where they should be, and fat where you want it—hams, shoulders and jowls, lean, muscular and delicate—broadsides the best of mess. Call them English or British, or what you please, the Berkshires are all they are cracked up to be.

Now, Friend Duthan, as they say the Connecticut people are the best educated of all the world, why should not we keep our hogs as much above *all others* in that particular? The science of Hogology in England has done wonders, far beyond Craniology or Phrenology—and we never can be up to the British in that science till we have a *Hogological Institute*.—But there's such a confounded notion in our country of running every thing into Old Schoolism, New Schoolism, Millerism, Puseyism, Perfectionism, Sociniamism, and every sort of isms, that I dare say such an institute would soon be upset by some *ism* or other. The professors would be getting by the ears about the doctrines, or some other principles in Bumpology, and frustrate the whole plan. But I should have no objections, however, to a little perfectionism in such an institute, for the Berkshire family are considered a good deal in that line now; and I think it would go much better in Hogoly than Theology, if they would not spin it too fine—for its just what Connecticut wants.

Now, Friend Duthan, think of this matter, for I must conclude this long concern by summing up my ideas in a sentiment for the occasion. "*The Berkshire Family*—Long lives and perfection to their posterity." Excuse my verbosity on this favorite topic of yours and mine, and believe me sincerely,

Your friend,

Obadiah Fairflax.

Central New York Farmer.

Ploughing for Corn.—The American Farmer says:—In ploughing up corn and oats ground, the farmer should neither spare his team or his plough, as the deeper he goes the better prepared will his soil be to sustain the crop sown upon it. It is a fact that cannot be disputed, that corn planted on ground deeply ploughed, always stands drought better, looks green and healthy longer, and nine times out of ten will yield more fodder add more grain, than that which is planted in shallow plowed ground. There is no mystery as to the reason; it is as obvious as that two and two make four. The roots penetrate beyond the depth at which, by evaporation, earth becomes deprived of its moisture, and there find in store for them that necessary ingredient to healthful vegetation, and thus escape from the evil of being parched up for the want of water.

Cure for Worts in Horses and Cattle.—A valuable friend of great experience in horses and cattle, (says the British American Cultivator,) and who has imported and bred many of the best in the United States, says that a strong wash made of pearlash and water, applied thrice a day, will remove tumors and worts.

Cultivation of the Turnep.—These are usually sowed, says a Mississippi correspondent of the American Agriculturist, here in August and September, on ground enriched by penning the cows and other stock upon it some time previously, or what is still better, on a piece of newly cleared land. But I prefer to them, for cows, *raw* sweet potatoes and cooked cotton seed.

If you would teach your cattle to be mischievous, put up a low or a slender fenee at first, and raise or strenghten it as they become expert in jumping.

AUGUSTA MARKET.

Tuesday p. m., April 18.

Cotton—Since our report of last Tuesday evening our cotton market has been very quiet, with but little doing, and no change save that which always marks a dull, inactive market; we therefore continue to quote 4 to 6¼ cents as extremes of the market—principal sales 4¾ to 5¼ cents.

Exchange—The market is abundantly supplied with exchange, which is sold at par on Charleston, Savannah and all the Northern cities. Central money ranges from 25 to 30 ℔ cent discount. State 6 ℔ cent Bonds are in demand at 50 cents on the dollar. Alabama notes 20 @ 25 ℔ cent discount.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

Advertisements pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞Post Masters are authorized to receive and forward money free of postage.

☞All communications must be post paid.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., APRIL 26, 1843. No. 8.

MR. FOOTE'S PRIZE ESSAY.

"A good agriculturist will neglect no means of forming dung heaps; it ought to be his first and daily care; for without dung there is no harvest."—*Chaptal.*

PRELIMINARY PROPOSITIONS.

That vegetation annually appropriates to itself, and thus removes from the soil, a certain amount of nutritive principles; and that the removal of a succession of crops, without some compensation in the shape of manures, will gradually impoverish, and, if carried far enough, ultimately exhaust the soil, are propositions so manifestly true as to require no illustration.—We every where see that the progress last indicated, is sure to be followed by a gradual change in the color and texture of the soil, and by a proportionate diminution of its vegetable products, until, if not arrested, the final result is absolute sterility.

The truth of the converse of these propositions is equally evident. Take an old field which has been reduced to barrenness by an unrelenting system of cropping without compensation, and restore to it a portion of those vegetable matters by the abstraction of which its poverty has been occasioned, and amendment is at once the consequence. Repeat the operation and a further progress towards fertility is made; extend it sufficiently far, and the face of nature is entirely renewed, and every symptom of a full recovery exhibited.

From these, and other kindred considerations readily suggested to the reflecting mind, we draw the following

INFERENCES.

1. That the appropriate food of vegetation is for the most part, neither more nor less than the ultimate results of vegetation itself, modified by the action of the animal organism and the several processes of fermentation.

2. That a limited amount only of the food of vegetation is contained in any given quantity of soil.

3. That a single crop cannot be removed from the soil, without diminishing, to a certain extent, its capabilities for supporting vegetable life.

4. That an uninterrupted cropping of any given portion of soil, without remuneration, will at length infallibly reduce it to sterility.

5. That the original fertility of any given portion of soil can only be maintained by faithfully restoring to it, in the shape of manures, an amount of vegetable matter equal to that which is annually abstracted from it.

6. That an *impoverished* soil can only be *restored* to its original fertility by the application to it of an amount of vegetable matter *greater* than that which is annually taken from it.

7. The most exhausted lands cannot only be regenerated, by sufficiently increasing the proportion of vegetable matter in the soil, but raised above the highest point of their original fertility.

8. That the deteriorated condition of the major part of our cultivated soil, is proof conclusive that all the resources of the farm have not, in general, been put in requisition.

9. That the secret of all good farming lies in the skillful management and judicious applica- of *home made manures.*

10. That it is of the highest importance to the agriculturist to study more carefully the nature of the soil, the wants of vegetable life, and the mutual relations and dependances of the soil and vegetation; and above all to cast about him and explore the sources of those animal, vegetable and mineral substances, the proper application of which to his cultivated fields, is not only an indispensable prerequisite to their increased fertility, but the certain harbinger if coupled with economy, of competence at least, if not of affluence.

DEFINITION OF MANURE.

Manure is a term of almost unlimited application—embracing an immense number and variety of substances—including, indeed, whatever can be named in the animal, vegetable and mineral kingdoms capable of improving and fertilizing the soil. Says the author of British Husbandry, "Any thing whatever may be called manure, which, when applied to the soil, rectifies its defects, corrects any bad quality, or either stimulates it to yield or stores it with nutriment." Any class of so heterogeneous a mass of substances which should at once prove satisfactory to the agricultural chemist, and intelligible to the merely practical farmer, cannot, in the present state of agricultural science, be attempted with any prospect of success. A practical classification alone, however, would seem to be called for on the present occasion, and that which is regarded as the simplest will be chosen.

CLASSIFICATION OF MANURES.

From the earliest speculations on the nature of manures, down to a very recent period, manures have been divided into two classes, nutrative and stimulative, or such as furnish the direct food of plants, and those which act as stimulants, or excite to take up and assimilate such kinds of food as is presented to them. In the first class have been placed all decayed and vegetable matter, farm-yard manures, animal excrements, night soil, and such other matters as having been derived from, are considered as capable of being reconverted into vegetable matter. In the second class it has been the custom to place gypsum, lime, such salts as are found to produce a favorable effect on vegetation, as the phosphates of lime in bones, and the nitrates existing in saltpetre, soda, &c.—(Albany Cultivator, vol. 8, p. 95.) To these may be added a third class, consisting of variable mixtures from the two former with several kinds of earth, and denominated composts. Thus we have the simple classification of all the manures into, 1st, *Nutrative Manures*, 2d, *Stimulative Manures*, and 3d, *Composts.*

NUTRATIVE MANURES.

The great depositories of the manures of this class are, the *barnyard*, the *piggery* and the *privy vault*—each of which will claim our attention, for a moment, in relation to the causes which operate to diminish the amount and value of their contents.

CAUSES OF WASTE.

How, then, are the contents of these depositories chiefly liable to waste? We answer, 1st. By *infiltration*, or soaking away into the earth; 2d. By *evaporation*, or being taken up by the sun and winds; 3d. By excessive *fermentation*, in which the heaps accumulate so great a degree of heat as to dissolve the salts which they contain, and dissipate them in the form of gaseous exhalations; and 4th, by *drainage*, or flowing away in the currents of water which are suffered but too often to despoil our barnyards of their richest treasures, and to defile our highways, and clog up our ditches with that which might otherwise fatten our cornfields.

REMEDY FOR DRAINAGE.

To close effectually the last named wastegate, it is only necessary to excavate the central portions of the yard as to form a sufficient reservoir for the liquids that will naturally find their way into it, and carefully convey away the droppings from the roofs of the buildings, by good conductors, and to turn the course of any superfluous waters from higher grounds, by effective trenches.

REMEDIES FOR INFILTRATION AND EVAPORATION.

To guard against infiltration, let the yard, and especially the excavated portions of it, receive a thorough coating (if nature has not been beforehand in supplying one,) of the purest *clay* at command; and to escape the mischiefs of evaporation, furnish it with an abundance of litter, such as refuse straw, oats, weeds and leaves from the forest, together with muck, surface soil from the road sides, hedges and ditches, or any other convenient matters of a porous nature, to absorb the liquids, and protect the whole mass from the influences of the atmosphere. A further security will still be found in occasionally strewing the yard with plaster, which, by combining with the volatile portions of the manure, and converting them into salts not volatile, will rob the atmosphere of its prey.

REMEDY FOR FERMENTATION.

Having taken the above precautions, little danger need be apprehended from excessive fermentation, except in case of considerable piles of horse dung; and here it will be very easy to avert the evil, either by occasionally spreading open the heaps, or, what is far better, by interlarding them at proper intervals, with muck or surface soil, which will not only effect the object in question, but absorbing the juices of the pile, become of equal value with the dung.

VALUE OF LIQUID MANURE.

It will readily be perceived that the principal effort of the farmer, in the preservation of his manures, must be directed to their *liquid* portions—these portions not only being by far the most exposed to loss, but possessing *a superiority in value which renders their loss irreparable.* This last sentiment, involving as it does a subject of vital interest in agriculture, we shall take the liberty of illustrating by the introduction of several authorities.

"The greatest value should be attached to the liquid excrements of man and animals, when a manure is desired which shall supply nitrogen to the soil. The greatest part of a superabundant crop, or, in other words, the increase of growth which is in our power, can be obtained exclusively by their means. When it is considered that with every pound of ammonia that escapes, a loss of sixty pounds of corn is sustained, and that with every pound of urine a pound of wheat might be produced, the difference with which these liquid excrements are regarded is quite incomprehensible. In most pla-

ces only the solid excrements impregnated with the liquid are used, and the dung hills containing these are protected neither from evaporation nor from rain. The solid excrements contain the insoluble, the liquids all the soluble phosphates, and the latter contain likewise all the potash which existed as organic salt in the plants consumed by the animal."—*Liebig's Organic Chemistry, pp.* 191.

"Liquid manure consists in a great degree of the urine of various animals, which during its decomposition, exhales a larger quantity of ammonia than any other species of excrement.—Now all kinds of corn contain nitrogen, and consequently any manure which yields a ready supply of ammonia, must cause a fuller developement of those parts of the plants which are of the greatest use to man. Even the kind of animal manure usually employed in this country owes its efficacy, so far as it is dependent on the ammonia present, to the urine, rather than to the solid excrement of which it is made up, and hence becomes materially deteriorated in this respect, when the more liquid portions are allowed to drain off from it."—*Danby's Lectures on Agriculture.*

"The quantity of liquid manure produced by one cow annually, is equal to fertilizing 1¼ acres of ground, producing effects as durable as do the solid evacuations. A cord of loam, saturated with urine, is equal to a cord of the best rolled dung. If the liquid and solid evacuations, including the litter, are kept separate, and soaking up the liquid by loam, it has been found they will manure land, in proportion by bulk of 7 liquid to 6 solid, while their actual value is as 2 to 1. One hundred pounds of cow's urine afford 25 lbs. of the most powerful salts which have ever been used by farmers. The simple statement then in figures, of the difference in value of the solid and liquid evacuations of a cow, should impress upon all the importance of saving the last in preference to the first.—*Dana's Muck Manual, p.* 171.

"Urine is always a most valuable manure.—No farmer should permit it to run to waste, but should so prepare his cattle yard by loam or swamp muck, and by plaster, as to save these invaluable products of his stables, and of his own dwelling. As the urine is commonly mixed with the solid excrements in the barn yard or cattle yard, it increases the value of this manure, it promotes its decay, and adds its own salts; but if the whole is exposed to the influence of atmospheric agents, it facilitates their action, and aids in depreciating its value; hence it is generally wholly lost to the farm. Farmers ought to know this, and to be apprized of the fact that at least one-half of their manure is wasted."—*Gray's Elements of Agriculture, p.* 502.

"Upon nearly all our farms the dung of quadrupeds is exposed to the open air, without the protection of a shed, as soon as it is removed from the stables; and is thus washed by the rains, which carry off all the salts, urine and soluble juices, and form at the foot of the mass a rivulet of blackish fluid, which is either wholly evaporated or lost in the ground. In proportion as fermentation advances, new soluble combinations are formed, so that all the nutritive and stimulating principles of the dung gradually disappears, till there remain only some weak portions of the manure, intermingled with stalks of straw which have lost all their goodness.—*Chaptal's Agricultural Chemistry, p.* 55.

A VALUABLE HINT.

"To remedy as much as possible an abuse so injurious to agriculture, it is necessary at least to dig a deep ditch to receive all the juices which flow from the dunghill, in order that they may be used in the spring on upon the corn or grass lands; or that they may be preserved to water the grass lands with after the first mowing. A large cask fixed upon a small cart, and which can be filled by means of a hand pump, is sufficient for this purpose. Beneath the tap of the cask must be fitted a narrow chest about four feet long, with the bottom pierced with holes, through which the liquor may be scattered.—This mode of watering, when used after mowing, produces wonderful effects upon the crop of the following year."—*Ib.*

AN EXPERIMENT.

In confirmation of the statement last quoted, the writer may be permitted to notice an experiment with liquid manure made by himself during the past year. Some 150 gallons of liquid were dipped in the month of October, from an excavation beneath his horse stable, and evenly distributed over a small area (perhaps 20 square rods,) of old meadow land, the soil a stiff clay loam, on which but little grass had grown for four or five years. When that area was mowed about the first of August last, it was judged to yield at the rate of at least three tons to the acre! An increase of certainly not less than five to one, and attributable to no other assignable cause than that dressing of liquid manure, of which too a considerable portion must have been made of water.

[To be continued.]

BOMMER'S MANURE—NO HUMBUG.

The invention of Mr. Bommer is presented to the public under circumstances which ought to inspire confidence. If we were wholly dependent on Mr. Bommer and his agents for information respecting the efficiency and utility of his method, we might even in this case, regard it as entitled to a candid investigation, especially when it is understood that we know nothing in their characters calculated to excite our suspicions, or in the system of the process, incompatible with the principles of sound philosophy. As it regards Mr. Bommer's personal character, it may be safely asserted, that we know nothing against it, while the valuable improvement which he has introduced among the agriculturists of our country, very naturally inspires us with sentiments of profound respect for him as a gentleman of scientific research, and of a discriminating judgment. His theory has past the ordeal of a careful examination by disinterested gentlemen, whose attainments in science pre-eminently qualified them to trace its harmony with the most approved principles of philosophy. The practical utility of the system has been tested both by public and private experiments, and in every case where the principles of the theory have been fairly carried out, it has resulted with complete success. The advantages of the method are so diversified that they are not likely to be duly appreciated without a careful examination. While I shall take it for granted, that the importance of nutritious manure is generally acknowledged by the farmers of New England, it must be conceded, that in a majority of cases essential losses are sustained in this article for the want of a well adjusted system. The method of Mr. Bommer furnishes a system of the most rigid economy in saving every thing that is available, and in using all to the greatest advantage. The expedition with which decomposition is carried on by this method, has very justly attracted the attention of the public, and presents inducements for general adoption, which it would seem that the most inveterate prejudice could not resist.

If, in any case, it may be asserted with truth, that "time is money," it is emphatically true in respect to the time which is saved by this rapid process in converting articles, which are frequently wasted, into the most valuable manure, in a few days, instead of requiring a year to consummate the object in a manner far less effectual. It is certainly no trifling advantage which is derived from this method, that the germinating powers of all weeds, submitted to decomposition by this process, will be utterly destroyed; and that yard or stable manure, in which foul seed is suspected to exist, may be essentially improved in quality by this mode of management, while every kind of seed in the manure will be incapable of vegetating. In locations where sea-weeds or other vegetable matters are easily obtained, which are difficult to decompose by any ordinary process, Mr. Bommer's method must prove an inestimable benefit to such as avail themselves of its use. But if we add to the above the advantages of earth and liquid manures, and also Mr. Bommer's plan of augmenting stable or yard manure, and the process which will soon be communicated to the purchasers of his method of a cheap and expeditious mode of converting muck and peat into good manure, it will be difficult to conceive of the amount of profit which will result to community if these improvements should be generally adopted.—*Con. Farmer's Gazette.*

MANAGEMENT OF MANURE.

We remember the time when farmers used to let their heaps of manure remain through the summer, fermenting and sending off the gases, which are the finest and most valuable parts of the manure. Sometimes the heap would be nearly hot enough to produce spontaneous combustion. We once put some potatoes in a heap of fermenting manure to sprout them, and in a few days, on examination, we found that they were *done*, being completely roasted.

Besides the great waste from fermentation, the manure was drenched with rains; and the soluble parts, the best that remained, were carried away, and frequently deposited where they were not needed. Thus by "fire and flood" all the most valuable parts of the manure were dissipated and carried away. Then the manure was black and mellow, and farmers considered it in fine condition for Indian corn or other crops for the next season. So it was hauled out in the fall, and deposited in the field for that purpose. How much was lost in this way we cannot tell, perhaps one third by the escape of gases, and another third might be carried away in solution, for the stream from the manure was dark and rich.

Manure should never ferment without being well covered with loam or some substance to absorb the gases; and when applied to the soil, it should be covered immediately; and if the soil be light and porous it should be covered a good depth or the gases will escape. If manure in the heap is likely to ferment before it can be conveniently applied to the soil, and it be not convenient to cover it with loam, or anything to receive and retain the gases, it may be overhauled and exposed to the air to keep it cool. It is better to spread out manure before fermentation commences, though it will lose something by being thus exposed to the air, than to let it remain to heat in the heap. For when in a heap the decomposition is rapid and the loss great.—When spread out and exposed, the fermentation is slow and the loss in a given time comparatively small.

Some writers recommend preparing manure for crops by allowing it to ferment before applied to the soil, but this method is very injudicious, unless some method is taken to retain the gases. Partially decomposed manure is good to give plants an early start, but the support thus given soon fails, and if there be not other manure or rich soil, the plant fails in a measure before the crop is matured. We prefer applying manure before fermentation, that the gases may enrich the soil and make it light and mellow. In this case if there be not a rich soil to give the plants a start in the first of the year, it may be well to apply ashes or poudrette, or something to give them an early start, if any thing of the kind can be procured with economy.

We have found that though old manure gives the plant a good color and rapid growth in the first of the season, the crop is usually lighter than when manure is applied in its full strength, that gives an abundance of nutriment to the plants when the crop is matured, this being the time when it is most needed. When old manure, or fine compost can be conveniently mixed with new manure, they answer well, as one affords food for plants in the early part of the season, and the other in the latter part.

Boston Cultivator.

FRIENDLY ADVICE TO THE SMALL FARMER.

PRACTICAL DIRECTIONS FOR THE PLACE AND MANAGEMENT OF THE DUNG HEAP.

Farmers have generally found out the advantage of having a dung pit instead of a dung heap; but still the rich drainage of the dung is much of it allowed to run away. The urine from the stables, &c., does not half of it run into the dung, though it is the best partt,he essence of the whole; and the privy manure, which is better still, is mostly neglected altogether.

All drainings from the stables, cow houses and styes, should run into the pit, and the overflowings should be caught in another pit, to throw back in dry weather.

The following is a cheap and effectual method of doing all this:

When convenient, the pit should be on the north side of a wall or of some trees, to shade off the sun; or under shed, to keep off both wind and rain. But these advantages cannot always be had without too much cost.

Having selected the best place for your pit, first lay in way soil, peat, or any soil as different as possible from that of your farm, and give it a hollow surface like a great tea sauser. Upon this lay potato stalks, and any other vegetable matters, easy to ferment, and hereupon a layer of dung. Next a layer of vegetable matter, as peat, turf, bark, rotten weeds, ferns, leaves or any king of dead vegetable, to increase your quantity; and so every week, cover your dung from the stables, styes, &c., with three or four times as much dead vegetable matter; thus making up your heap in alternate layers. The urine should all run into the pit from stables and all, by narrow drains, where it will not be much exposed to evaporation; and another such drain should lead from it to a lower pit, to catch the overflowings when there are any, and keep them to throw back upon the dung in dry times. This lower pit should be deeper and smaller than the other, and must never be allowed to overflow, as that would be waste. It may contain cabbage stumps and other things difficult to work, which may be thrown back upon the heap as they rot.

The lower pit may be used as a store of liquid manure, for watering your corn in May or June; which gives it a start, and much strengthens its growth. In leaky ground, the bottom of the pits should be *staunched* with clay, and stones or gravel stamped in to harden it.

The privy should diseharge into the large pit, if possible, or else into the small one; and coal ashes (but not wood ashes) are good to throw where this comes out. Saw dust, or turf dust from the stacks, do very well. House washings, as soap-suds, &c. should also be thrown on the heap; but the wash of the country and heavy floods of rain should not be allowed to enter it, but be led into the meadows by other channels.

In wet seasons the top should be slanted to turn off the rain.

Each layer of dung being covered with a layer of peat or other dead vegetable matter, the whole heap, when finished, should be crusted over with way soil or other earth, to retain the vapors.

The fermentation will be slower or quicker, as it is more or less covered and compressed.

Wherever your heaps are made, whether in the yard or the field, give them a bed of some sort to absorb the drainage, and crust them over with soil, and mix up with the dung before spreading. The drainage carries down the strength of the heap; sometimes enough to kill the seed in the place where the heap stood; whilst it would have been of the greatest benefit if spread out with the dung.—*Ply. Herald.*

Cultivation of Wheat.—We find in the Farmers' Magazine, that the Chelmsford Club decide, from experience, that salt and lime applied to the seed of wheat, (probably in the same manner as we do here in the U. States,) are destructive to the slug and wire-worm; and that lime is beneficial to the crop, both before and after sowing it; that a good clover ley is best calculated to produce a good crop of wheat, and a bean or pea etch is the next best preparation.

LIMING.—RUST.

Sandy Spring, Maryland.

Notwithstanding "it is discouraging to preach to a deaf congregation," yet, whenever it appears from its effect, there is any improvement in the morals or practices of the congregation, it ought by all means to be persevered in; and even if the improvement is but slight, it does not lessen the obligation on those who may have a knowledge of facts which may be of use to others, to communicate them. In accordance with these views, I have been induced to throw in my mite, by way of furnishing a few facts with regard to the use and effects of lime in this neighborhood, to which I find some reference made in a letter from the present editor to William M. Peyton, of Roanoke, published in the January number, new series, Farmers' Register.

From twelve to fifteen years since, one of our farmers, living on some of the most unproductive land in our county, situated about six miles from the limestone quarries, was induced to try the effects of lime in larger quantities than he had applied it some thirty years before. He had then become discouraged, by seeing no effect from it, owing, as he afterwards found, to the small quantity used, say about twenty-five bushels to the acre. He soon found the beneficial effect very great, and he wanted no other stimulant than the increase of crops, to induce him to persist in its application. From the example of the individual above alluded to, I think is mainly attributable the great improvement in the land and crops in this neighborhood from the use of lime.

There are now within five miles of our point more than twenty lime kilns, and all have been erected within the time above mentioned, mostly all of which belong to farmers, who haul the stone from one to seven miles, and burn it at home, with their own wood; deeming it a cheaper and better plan than to purchase the lime.—The greater part of them have purchased quarries, for some of which as high as $800 and $1000 per acre has been paid. I have one containing rather less than one quarter of an acre, for which, I have no doubt, I could to-morrow, notwithstanding the hard times, obtain $300, which would be at the rate of more than $1200 per acre. And this from men who have worked for their money, and not disposed to expend it on a "bubble."

Now as to the effects of lime. I think it may be safely asserted, that upon an average, throughout the neighborhood, the application of fifty bushels to the acre, after the expiration of from one to three years, has trebled the crops; in some instances much more, and in a few possibly less. Various quantities have been applied, from 50 to 100 bushels, but not more than the latter quantity, to much extent, that I am aware of. My own opinion is in favor of the largest quantity, particularly of the kind of lime that we have access to, which has a good deal of sand in it, and I would put on two, or even three hundred bushels to the acre, without any fear of injury, either to the present or future crops. I have seen clover growing luxuriantly out of a bed of lime, (where a lump had slaeked after spreading,) of 500 or 1000 bushels to the acre.

I will now state a few results from my own application of lime.

About ten years since, I had some lime put, by way of experiment, on some very poor land, at the rate of not more than 50 bushels to the acre. I had recently purchased it, and that the land was poor, may be inferred from the price I paid for it; say $2 05 per acre. It had been always rented out. It had been cultivated under the *two shift* system that prevails here to a great extent; that is, corn alternate with oats. In the spring of 1841 I took possession. This piece was sowed with oats and clover, and at harvest, there was at least three bushels of oats on the limed ground, to one on that adjoining, and a much greater difference in the clover. By the fall of 1842, there was scarcely a sprig of clover on the ground not limed, and on that limed it is now well set.

Another piece of ground I ploughed in the spring of 1841, containing rather less than one and a half acres, two thirds of which had been cultivated under the two shift system, the greater part of the time for the last half century: the balance had grown up with sassafras bushes and sedge grass, and had probably become so poor some twenty or twenty five years ago, that it was given up. After ploughing the whole about six inches deep, I spread 100 bushels of lime to the acre, together with the manure from the straw of about 70 bushels of oats, and a few bushels of slacked ashes which the tenant had left. It was then well harrowed and planted in potatoes. The product about 100 bushels. I then seeded it with wheat, with a slight dressing of manure, obtained principally from penning five head of cattle at night through the summer, and at harvest cut nearly 19 bushels of wheat to the acre. It was somewhat affected with rust, but not so as to injure the grain, for that was as fine and plump as I almost ever saw. Whether the lime had the effect to prevent its being more injured by rust, I cannot say, but of this I am confident, that some of my neighbors, whose land previous to liming was as good or better than mine, did not raise more than half the quantity, and that inferior in quality, being much injured by rust.

The theory of lime affording nutriment to the grain of wheat more particularly than to the straw, is strongly supported by facts, and as it regards clover, I have recently been informed by the owner of a mill for getting out the seed, that the clover seed was more perfect raised on limed ground, and was worth from $1 to $1 50 more per bushel, than that grown on some of the best land in the country without lime.

But if I were to state one-fourth of the successful results from the use of lime in this part of the country, the limits of a Register would hardly suffice, and I will therefore conclude this with a remark made some years since, by Dr. Black of Delaware, and in which I fully concur, viz: "Although at first view it seems paradoxical, that lime makes a stiff soil light, and a light soil stiff, comparatively speaking this is certainly so. It makes all soils rich, and this merges all distinctions."—*Farmers' Register.*

Cutting Asparagus.—I stumbled accidentally, and from carelessness, several years since upon the plan of cutting Asparagus, which I have since recommended very highly; which is not to cut it below the ground, as usual, but to allow it to grow from fifteen inches to two or three feet long, and cut off about one foot of the top. By doing so, almost the whole will be equally tender and well flavored; while in the old way, only an inch or two is eatable. It is a fact, that Asparagus does not become tender until it turns green. I always thought it a poor vegetable, until I cultivated it, and gathered it as above; and now I find it one of the best. I think also, that there is a great deal more fuss, (pardon the word, as unclassical, but very expressive,) made about the cultivation of Asparagus, than there is any need for. I would say, make beds three feet apart, as if for cotton, lay your roots about eighteen inches apart in the alley, haul the bed back upon them, cover them well with fresh stable or other strong manure, immediately and every year; and if they are planted early in the winter, you may cut them twelve or fourteen months after. They may not possibly be as large as candles, but none the less palatable for that, nor bear any the worse for it—at least I have not found it so. If you live on a sea-island, and can make a bed in salt land, you will find it thrive to your satisfaction; and if you live in the interior, empty all refuse-salt and salt substances upon your bed as its specific manure.—*Southern Agriculturalist.*

There are cases, in which a little common sense is of more worth than a great deal of calculation.

GAMA GRASS.

To the Editor of the American Farmer:

DEAR SIR—I have a half pint of Gama Grass seed, sent me by a friend, and small as is the quantity, I estimate it as well worth sowing and taking good care of. I saw some few years ago in some newspaper, I think, some account of an acre of this grass seed in Alabama, which yielded near three tons of hay at a single mowing, and was mown six or seven times a year, (in that climate)—I have searched your American Farmer for years back, including those published many years ago, and the Albany Cultivator for three or four years back, and can find nothing about Gama Grass—and have to request you, or through you, some of your many correspondents, some information about it, such as, in what kind of soil (wet or dry) should it be sown? at what period? how much seed to an acre? the best mode of making good hay of it? where the seed can be procured? and other information that may be useful to one desirous to raise it and make it beneficial—how to save the seed, and when? how much hay should it yield per acre? how often cut? the cost of the seed?—And the same information and description is desired of Lucerne.

Your compliance through your very valuable "Farmer," will oblige your subscriber and obedient servant, WM. COOK.

Describe the seed, their size, shape, color,&c.

REPLY TO THE ABOVE.

The American Farmer is full of information upon the subject of the cultivation and produce of Gama Grass—but as our correspondent may, possibly, not have convenient access to the volumes containing it, we will briefly sketch such parts as may be necessary to subserve his purpose, after first answering the questions submitted to us.

Question 1.—In what kind of soil (wet or dry) should it be sown?

Answer—It will grow in any soil, and we have seen a very luxuriant crop in a piece of wet meadow land, where it had been placed from necessity; though its growth was very evidently improved by a thorough draining, to which the land was subsequently subjected. The better the soil, the more luxuriant will the grass grow. If we were to select a soil for it, we should choose the richest and deepest loam on our place; for, from the great depth to which the roots penetrate, the rapid growth of the plant, and the frequency of its admitting of being cut, it stands to reason that it should have all the advantages of depth and richness of soil, and be unstintingly aided by copious supplies of manure. In the preparation of the soil, care must be taken to provide against weeds; and if it be not naturally calcareous, or have been limed, lime should be supplied, as like all other grasses and grains, it delights in that soil best where lime abounds.

Ques. 2.—When should it be planted?

Ans.—As soon in the spring as the land can be got in good tilth. Connected with this part of the subject, we would remark, that after manuring the soil freely, it should be ploughed as deep as a strong team can well go; that the ground must then be harrowed until a fine tilth is produced, when it must be rolled.

Ques. 3.—How much seed per acre?

Ans.—We have never seen the quantity of seed allotted to an acre named; but, from an acquaintance with the size of the seed, should presume that half a bushel would be enough. The customary manner and distance of planting, is in rows, 18 inches apart, the plants 12 inches asunder, so that it would take 29,046 seed to plant an acre; but as many of the seed do not come up, we think it best to plant the seed much closer in the row, say, four inches only apart.

Ques. 4.—What is the best method of making hay of it?

Ans.—Upon this head there is no difficulty whatever, as it is as easily cured as any other grass, and requires no more drying than timothy, orchard grass, or red top. In stacking it away, a peck of salt to the ton of hay, would greatly promote its acceptability to the stock.

Ques. 5.—Where can the seed be procured?

Ans.—We procure it frequently in Charleston, S. C., where it doubtless can be now procured; but if our correspondent has half a pint of the seed, and it *be good*, we would advise him to make a beginning with that, as should they vegetate generally, they will afford him a good crop of seed next year, besides numerous plants for transplanting, as every bunch will bear subdividing, so as to allow him from 20 to 50 roots the succeeding spring, which, with the seed, will enable him to set out more than an acre the second year after commencing.

Ques. 6.—How often can you cut the hay?

Ans.—In Alabama, North and South Carolina and Mississippi, it has been cut as often as seven times in a season, and we should think, that in Bedford county, Va., from four to five cuttings in a season might be calculated upon, of from 15 to 18 inches in height. But to ensure this number, every cutting should be followed by a top dressing of some good rich compost manure, as moul l or rotten barn yard manure, and ashes, say ten bushels of either of the two first, to two of the latter, to be worked in between the rows with the hoe.

Ques. 7.—How much hay will it yield to the acre?

Ans.—This is a question we are not prepared to answer, as our experience is at fault upon this point; but here our good and respected friend, Dr. Magoffin, of Alabama, is a resource to which we can recur with a surety of obtaining the truth. He says, that "at each cutting a number of the *smallest* branches were weighed, and also of the *largest*. None found less than 5 lbs. and many 15 lbs., and some 16 and 17 lbs. per plant at *each* cutting—and *seven* cuttings in the season." He says, also, that he has dried it into hay at a loss of a little more than one-half in weight—viz: that 14 lbs of grass gave 6 lbs. dried hay. Now then, if we take the last yield of a bunch or root, that is 5 lbs., for our guide, five such cuttings would give us 25 lbs. the season per root, of grass; at the rate of loss named by Dr. Magoffin, it would give an aggregate of 10 lbs. of hay at five cuttings, during the season, for each bunch, so that as there would be 29,040 bunches on an acre, the acre, at that rate would yield 290,400 lbs. of hay; but suppose we take the fourth of that quantity as the probable product, and we have 36¼ tons as the yield of the acre—and if we carry the reduction still further, and take the fourth of 36¼ we will still have above nine tons to the acre—if, however, we take Mr. Magoffin's minimum of 5 lbs. to the bunch, we get the incredible quantity of 145 1-5 tons. That it is the most productive grass in cultivation, when properly cared for, we have no question; that it is eminently calculated for a warm climate we are equally certain, and believe also, that it will be well relished by all kinds of stock, if cut before it becomes too rank. When intended for hay, it should be cut at least once a month, the first cutting to take place when the grass may be 15 inches high. But as our correspondent and every other intelligent reader will admit, to get the most out of this grass, it must be grown under the most favorable circumstances of situation, soil, preparation of soil, cleanliness of culture and heavy manuring. The soil in which it may be grown, should have lime in it, be heavily manured before ploughing, be moderately top-dressed after every cutting; the weeds must be kept down by hand hoeweeding, and the ground be kept open to the influence of the elements.

The seed in the outside covering are somewhat the shape of castor oil beans, though much smaller, of a dusky yellow cover.

In preparing them for planting, they should have four times their quantity of hot water poured over them, and be permitted to remain therein for forty-eight hours, when they may be planted in a bed in rows 18 inches apart, the seed to be drilled at 12 inches asunder. When they first come up, they look like corn. They must be kept clean of weeds and other intruders by hoeing and hand-weeding the first season.

It may be said to be a matter of great labor to set a meadow with Gama grass, and so it is; but when one reflects, that when once set, it will last for 70 years, and that one acre will give as much hay as *ten* set in any other grass, the *trouble*, *labor* and *cost* should not be permitted to preponderate against the manifold advantages which belong to its culture.

Now what would be the labor attending the setting of an acre, the plants being grown? Not much more than planting an acre in corn. With two boys, ten years old, with the plants in baskets, to drop them in the furrows, 12 inches apart, and two men to cover with the hoe and press the earth with its back, we would agree to plant out an acre in a day, and when this would be done, we would indulge in the comfortable reflection, that we had perfected a work which would last for three-score years and ten; that both ourself and our children were secured in hay for our stock during our lives. Notwithstanding the immense yield of this grass—notwithstanding its long continuance—notwithstanding it is nutritive to and relished by stock of all kinds, such is the aversion of the great body of agriculturists to incurring any *extra* labor, that we fear it never will be successfully introduced. Again, we have heard the objection raised against it that it required to be cut too often; or, in other words, that it was too productive; for the objection resolves itself into this, let it be twisted as it may.

So far as our personal knowledge of this grass extends, we think that it delights in a warm climate, and that probably it could not be cultivated to advantage in the Northern and Eastern States. To the Southern States we look upon it as a God-send, as it would, if its culture were generally attended to, enable their planters to amply supply themselves, not only with grass for soiling their stock through the summer, but with abundance of good provender for winter.—*American Farmer.*

VALUE OF THE AGRICULTURAL PRODUCTS OF THE UNITED STATES IN 1842.—The American Farmer publishes the following estimate of the value of agricultural products of the U. States, which it says is based upon the "tabular estimate of the crops of 1842," made by the Commissioner of Patents in his Annual Report communicated to Congress. The prices set down are those which prevail in this market, or such as are supposed to be a fair average at other places. The actual prices here are designated by the letter *a*, those supposed by the letter *s*.

Articles of Produce.	Quantities of Produce.			Money value.	
Wheat,	102,371,340	bush.	at 75c	*a*	$76,738,005
Barley,	3,871,622	do	at 50c.	*a*	1,935,811
Oats,	150,833,617	do	at 22c.	*a*	33,194,325
Rye,	22,762,952	do	at 50c.	*s*	11,381,476
B'ckwheat	9,483,409	do	at 40c.	*s*	3,793,363
Ind'n Corn	441,829,246	do	at 42c.	*a*	185,568,283
Potatoes,	135,883,381	do	at 25c.	*a*	33,790,845
Hay,	14,053,335	tons	at $10	*s*	140,533,550
Flax and Hemp	158,569¾	do	at $120	*s*	19,028,370
Tobacco,	194,694,891	lbs.	at 6¼c,	*s*	12,169,330
Cotton,	684,333,231	do	at 8c.	*s*	54,666,658
Rice,	94,007,484	do	at 2¼c.	*s*	2,350,187
Silk Coons,	244,124	do	at 50c.	*a*	122,062
Sugar,	153,345,199	do	at 5c.	*a*	7,122,259
Wine,	130,748	gals	at 50c.	*s*	65,374
Supposed value of the above fifteen articles,					$582,639,968

Above is the value of the estimated products of fifteen articles only, the growth of 1842, amounting to six hundred millions of dollars; and yet, as a people, we are oppressed to the earth with pecuniary debts and difficulties, and almost without credit at home or abroad. Such a state of things is unparalleled in the history of the world, and it is useless to blink the question longer, as there can be no doubt but that

through the course of ruinous measures, tending to the derangement of the currency and the prostration of individual and public confidence, the interests of the farming and planting classes have been paralyzed.—*Balt. American.*

EXTRACTS FROM THE REPORT OF THE COMMISSIONER OF PATENTS

It may be well here, also, to allude to certain products not mentioned in the tabular estimate, which have been sometimes proposed as offering some encouragement to the agriculturist to engage in raising them, and thus add to the means of employing the labor which must be given to agriculture, and which, yet owing to the vast surplus of the grains, &c., above the home consumption, seems to promise but little profit.

One of these is broomcorn, which is much cultivated, and with success, in some towns on the Connecticut river, in Massachusetts.

We here annex an article from the appendix, which embraces much information on this subject, important in the South:

Broomcorn.—The North river kind is ordinarily the best crop; it is ten days earlier than the large kind, and yields about 750 pounds of the brush per acre—the brush meaning the dried panicles, cleaned of the seed, with eight to twelve inches of the stalk. The New Jersey, or large kind, yields a thousand or eleven hundred pounds of brush per acre. The stalks and seed are large. In good seasons this is the most profitable crop. Soil rich, alluvial lands are best adapted for the broomcorn, more especially if warmly situated, protected by hills, and well manured.

Method of planting.—The broomcorn is planted in rows, about two and a half or three feet apart, so that a horse may pass between them with a plough, or cultivator, or harrow. The hills in each row are from eighteen inches to two feet apart, or further, according to the quality of the soil. The quantity of seed to be planted is estimated very differently by different farmers—some say that half a peck is enough per acre, while others plant half a bushel, and some a bushel, in order to make it sure that the land shall be well stocked. The rule with some is to cast a teaspoonful, or thirty or forty seeds in a hill; the manure at the time of planting should be put into the hill, and old manure or compost is preferred, as being most free from worms.

Cultivation.—The broomcorn should be plowed and hoed three times; the last time when about three feet high, though some hoe it when it is six feet high, and when they are concealed by it as they are toiling in the field. The number of stalks in a hill should be from seven to ten. If there are only five or six stalks, they will be larger and coarser; if there are about eight, the bush will be finer and more valuable. In the first hoeing, the supernumerary stalks should be pulled up.

Harvesting.—As the frost kills the seed, the broomcorn is harvested at the commencement of the first frost. The long stalks are bent down at two or two and a half feet from the ground; and by laying those of two rows across each other obliquely, a kind of table is made by every two rows with a passage between each table, for the convenience of harvesting. After drying for a few days, the brush is cut, leaving of the stalk from six to twelve inches. The longer it is cut, of course the more it will weigh; and, if the purchaser does not object, the benefit will accrue to the farmer. However, the dry stalk weighs but little; if its weight is excessive, the purchaser sometimes requires a deduction from the weight. As it is cut it is spread on the tables still further to dry. As it is carried into the barn, some bind it in sheaves; and this is a great convenience for the further operation of extracting the seed. Others throw the brush into the cart or wagon, unbound.

Scraping.—The process of extracting the seed is called "scraping the brush." Two iron horizontal scrapers are prepared—one moveable, to be elevated a little, so that a handful of brush may be introduced between them. The upper scraper is then pressed down with one hand, and the brush drawn through with the other, the seed being scraped off. This is the old method. A newly invented scraper is superseding the old one. It is an upright instrument, of elastic wood or steel, inserted in a bench of a convenient height for the operator.

A quantity of brush is taken in the hand and brought down upon the top of this instrument. As it is forced down, and drawn towards the body, it separates the elastic sticks from the central piece, but their elasticity presses sufficiently on the brush so that the seed is scraped off.

The advantage of this scraper is, that both hands may be applied to the brush instead of only one hand, as in the other kind, and the elastic power of nature is substituted for the pressure of one of the hands. The instrument also seems to double the scraping surface. This instrument was invented at Hartford. I have been told it has not been patented.

Product.—A common crop is 700 to 800 lbs. per acre. There have been raised 1000 and 1100 lbs. per acre, with 80 or 100 bushels of seed. The large kind grows 11 feet high.

Value of the crop.—About the year 1836 or 1837, the brush sold for twelve and a half cents a pound; and one farmer in Northampton sold his crop standing, unharvested, at $100 per acre. Since then the price has been decreasing. This year it has been four and five cents. At six cents, the farmer, for 800 pounds, gets $48 an acre, besides 60 or 70 bushels of seed, worth a third of a dollar a bushel—so that he receives $70 or upwards from an acre.

Good farmers regard the seed alone as equal to a crop of oats from the same land. Some land owners have rented their land for broomcorn at $25 per acre, they putting on five or six loads of manure.

One farmer who, a few years ago cultivated 50 acres in broomcorn, must have had an almost unprecedented income for a New England farmer.

Quantity.—In Northampton, probably 200 acres are raised; in Hatfield, 300; in Hadley, 400; in other towns, Whateley, Deerfield, Greenfield, Easthampton, South Hadley, Springfield, and Longmeadow, perhaps 300 or 400 acres more; in all, in the valley of the Connecticut, 1200 or 13 acres; the product, in brush and seed, worth about $100,000.

Manufacture of brooms.—Individuals tie up brooms with wire or twine. The expense is greater for materials and labor when wire is used.

The turned broomhandles cost, as delivered, only $1 a hundred—one cent each. The expense of other materials and labor in making a broom, is six cents, or the whole about seven cents. In a good broom, a pound and a half of brush is employed, which, at the present price of five cents, would be seven and a half cents, so that a broom made with wire costs now about fourteen and a half cents. A manufacturer recently went to Boston, and could get an offer of only twelve cents, or twelve dollars per hundred for his brooms; at which rate he could not afford to sell them, and chose to retain them.—Brooms are made with brush weighing three-quarters of a pound, one pound, one pound and a quarter, and one pound and a half. The brush is whitened by the manufacturer. It is placed in a large tight box, and bleached by the fumes of sulphur; but this process is said to weaken the brush. Who would think of whitening broom brush for beauty? Thus it is that fashion descends into the vale of life, and to the humblest of concerns. Why should not the house maid wield a beautiful broom, with white brush and variously interlaced wire, and polished and variously colored handle?

Miscellaneous.—A few remarks will be added, some of which were omitted in their proper places. If the stalks are cut before the seed is ripe they are better, stronger, more durable, than if cut after the seed is ripe. In this case, the farmer would lose the value of the seed. He of course would not submit to this loss, unless it is made up to him by the increased price of the brush.

The seed is used for feeding horses, cattle and swine. It is ground and mixed with Indian meal, and is regarded as excellent food; it weighs 40 lbs. a bushels.

Mr. Shipman, of Hadley, is the greatest manufacturer of brooms in the valley of the Connecticut. If he employs, on an average ten hands, and each hand makes 25 brooms per day, the number made in a year would be 78,000. It is said he has made 100,000.

The brush, when it is put in the barn, should be placed on a scaffold, so as to be exposed to a circulation of the air, that it may dry, and not mould. For all the purposes of use, a broom made with twine is equal to one made with wire; and a man can make several more of them in a day.

Mr. Shipman uses 300 to 400 pounds of large twine, at 20 to 30 cents a pound, and 2000 lbs. of small twine, at 31 cents. Perhaps he manufactures only an eighth part of the brooms manufactured in Hadley.

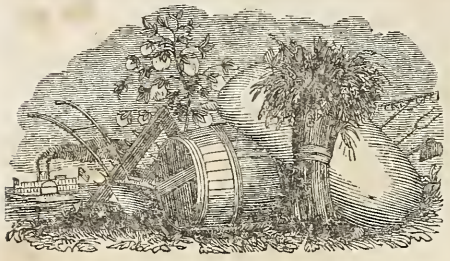
At the price of 20 cents, the price of brooms a few years ago, the broom manufacture of Hadley would thus amount to $160,000.

It is probable that the extended cultivation of the broomcorn will reduce the profits of this product to the average profits of good farming.

The Tomato.—The celebrity of this plan has become astonishing. A few years since prejudice reviled at its excellence with its most vindictive tauntings. Now, it is an article of so general popularity, scarcely a garded, or an apology for one is to be found where it is not cultivated, and almost every voice is loud in proclaiming its excellencies. The tomato has three kinds of varieties, to wit: the large common, the egg, and the golden drop. We prefer the two last kinds for culture as they are firmer, or more solid in their texture and more delicate in their flavor. The tomato may be started in a hot bed, or in boxes in the house in March. Then by care, large thrifty plants will be ready for putting out as soon as the season of frost is passed. They do not require a rich soil; this causes them to run too much to vine, but rather an excitement to push forward to perfection.—We know of no more sure effective to produce this than to put say half or a third of a common shovel full of hen or pigeon's dung in the hill. It is admirably calculated for pepper or for tomatoes.

After the early frost had killed the vines last fall, a friend of ours, of close observation and exact calculation, experimented by feeding the tomatoes that remained to her cows. They were readily eaten, and the quantity of milk was increased. This certainly adds another to the thousand and one uses to which they have been applied.—*Farmer's Cabinet.*

Necessity of a Change of Crops.—In a conversation the other day with an intelligent friend, I stated the remarkable fact, that if an animal were to be confined to one particular diet for a certain number of days, sickness, and eventually death must be the consequence; when he immediately applied the *rationale* of the fact to a subject at once so highly interesting and natural, that I cannot help recording it.—"Then," said he, "this shows at once the necessity of a change of food to the crop; or which is the same thing, a change of crop to the soil—a *rotation of crops*, as it is called." Now in this little remark, a volume is thrown open to our perusal, and by studying it, I believe we may derive information and advantages at present unknown and unappreciated; and in return for the many useful hints and very pleasant ideas that I am continually reaping and garnering up from the perusal of your paper, I offer the above in grateful acknowledgement.—*Farm. Cabinet*



WEDNESDAY, APRIL 26, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

THE PLANTER

Is the title of a new paper, the first number of which has just been issued by Messrs DUBOSE & JOHNSTON, at Columbia, S. C. It is a very neat folio, and to render it more interesting to every class of readers, it combines within its range, agriculture, miscellany and news. Subscription $2 50 per annum.

MR. FOOTE'S ESSAY.

In the present number we commence the publication of a Prize Essay on Manures, delivered by Mr. FOOTE, before the Berkshire County (Mass.) Agricultural Society, which we shall complete as rapidly as our limits will permit.—Mr. F. has devoted much time and labor to the investigation of this important branch of husbandry, and his essay, which cannot fail to be read with interest by every farmer who properly appreciates the value of manure, discovers considerable research, and is therefore entitled to the dispassionate consideration of every planter who desires to improve his land and thereby increase its productions. If the careful perusal of this document, which is the result of much investigation, research, and the actual experiments of the author, shall only excite a spirit of investigation and induce to a course of experiments, it will certainly accomplish much good for the improvement of Southern agriculture. For wherever a systematic course of experiment be adopted and persevered in, truths of greater or less value will certainly be developed, which must result in a proportionate ratio of benefit. Men must not expect the highest state of improvement, even by the most skilful, in a day or even a year; but they must enter upon a patient system of investigation, determined to prosecute it with all their energies, through a series of years. This, and this alone, can elevate the science of agriculture in the South, to that point it has attained in all sections of the world where a proper direction has been given to labor, aided by the lights of science. Such a course has attained the highest state of perfection in many parts of the old world, and there is no good reason why the same result cannot be attained among the planters of the South.—We have as much energy, enterprise and intelligence among the mass as is to be found elsewhere, and all we want is to bring to the labor patience and perseverance, and with the aid of the lights which those afford who are far in advance of us in the science of agriculture, success will certainly crown our efforts. Indeed, with the lights before us, there is a much stronger incentive to action, than could have existed with the pioneers in this great labor of experiment, research and investigation; for while theirs was literally an untrodden path in the vast region of speculative theories, ours is a beaten way, illumined by the lights of their experience, and holding out a promise of reward as certain as we employ the means to obtain it.

MULES.

We are indebted to "A PLANTER" for calling our attention to the list of premiums to be awarded by "*the Planters' Club of Hancock*," at their annual meeting, which we had placed on file for publication immediately after it appeared in the Milledgeville papers, as we did not receive it through any other medium. It will be found in this number of the "*Cultivator*."

We concur fully with "A Planter" as to the superiority of the mule over the common horse for agricultural purposes, and we doubt not that the omission to include them in the list of premiums, was the result of inadvertence rather than design on the part of the Club. In giving this expression of decided preference for the mule over the horse, we desire to be understood as refering exclusively to the better bred class of mules; for we have long thought that most of our planters who raise mules, are not only too indifferent as to the stock of the mares from which they produce mule colts, but many seem to have arrived at the conclusion, that after the colt is foaled it requires no farther care or attention until in its two year old form, when they are frequently required to perform the duties of a full grown horse or mule. In our opinion this is a most erroneous practice, and one of decidedly bad economy. To produce fine mules, too much attention cannot be bestowod in selecting the mares, which should be of the best stock that can be obtained—combining good blood, size and fine symmetry. Nor is this all: when the colt is weaned, it should not be left, as in too many cases it is, to seek its sustenance through the winter months almost entirely in pastures in which not a blade of nutritious food is to be gleaned. On the contrary, care should be taken to supply it with a sufficiency of nutritious provender to sustain and support it in a healthy, thriving condition, and when it has attained the usual age at which they are required to be broke to work, instead of the generation of half grown, rough looking dwarf mules which meets our observation on almost every farm and in every wagon, we should see a class of stock approximating very nearly the horse in size, equalling him in symmetry, a glossy coat of hair and quickness of gait, and surpassing him in powers of endurance, while they would require a smaller portion of food to sustain them and render them capable of discharging the same and even greater labor. Being an ardent admirer of that noblest of all animals, the horse, we have, for our opportunities of observation, been a somewhat close observer of the cross with the ass, and we have never, in a single instance, seen a well bred, highly formed mare, fail to produce a mule colt infinitely superior in gait, appearance, symmetry and disposition, to the common coarse mares from which they are generally produced. It is based upon the soundest principles of philosophy and common sense, and must impress itself with all the force its importance demands, upon the mind of every reflecting planter who attempts to raise mules for agricultural purposes.

For the Southern Cultivator.

JACKS, JINNYS AND MULES.

MR. EDITOR—I have been for sometime expecting to see the list of premiums offered by the annual fair of the Planters' Club of Hancock county, inserted in the columns of the "Cultivator," and have been disappointed; but in looking over the Georgia Journal to-day, I find the list of premiums which are to be awarded at Sparta, on Friday, the 3d day of November next. The list is long and I approve of it all, but it is to be regretted that the committee should have neglected or left out the Jack, Jinny and Mules; for among the planters of the South, and, I might say, of the United States, the economy and advantages of the mule over the horse are universally admitted. The Club has offered premiums and honors for the 1st, 2d, 3d, 4th and 5th best brood mares, fillies, colts, bulls, cows, hogs, pigs, &c. &c., until they get to stockings and gloves, and nothing said about the Jack, Jinny or Mules. Why make this distinction between the horse and mule? Offering the highest premium for the Stallion and say nothing of the Jack. The horse, costly and extravagant—the mule cheap and economical.

Taking all these things into consideration, would it not have been better to have offered the highest premium for the Jack or Mule, which, in every instance, is to the advantage of the planter. But lest some should say it is a notion of my own, allow me to recommend the report of a respectable committee of the Farmers' Society of Barnwell District, South Carolina.—They say that the annual expense of keeping a horse, is equal to his value. The same committee also states, that "a four year old horse will seldom sell for more than the expense of rearing him; that the superiority of the mule over the horse had long been appreciated by some of their most judicious planters; that two mules could be raised at less expense than one horse; that a mule is fit for service at an earlier period; if of sufficient size, will perform as much labor, and if attended to when first put to work, his gait and habits may be formed to suit the taste of the owner."

This report may be considered a most valuable document to the planters. I have owned mules and horses, and I can testify, in every instance, to the truth of their report; and, from repeated experiments, I have found that a largs size mule will not require by two thirds the food to keep him in good order that will be necessary for a large horse, performing the same extent of labor; and in no part of the country is the mule better adapted to all the purposes of husbandry for which the horse is used, than in our own State.

You will see that I am no hand with a pen—my ideas are in my head and I cannot well

shake them out at the end of my fingers. I have written this, hoping it might be the means of calling out others who are capable of writing; but I know planters are too apt to depend on others to attend to that which they should do themselves, and in this way much to their interest goes undone. I also hope it will have some influence with the Committee. The times are hard, and we should act for the interest of the community. A PLANTER.

Green county, Ga.

[We cheerfully insert the communication of our correspondent, and hope to hear from him often.—ED. SOUTH. CULT.]

For the Southern Cultivator.

GREEN COUNTY, GA., April 20, 1843.

Messrs. Jones—As the time has arrived that, in the old counties of Georgia, we must fall upon the plan of manuring and resuscitating our old (and I may say, much abused) lands, or meet a poor return for our still poorer mode of cultivating them. As the first step, I would say to farmers, commence the right way to make manure, and save what you make. As the stable lot is the proper place to form your dung heap, manure pit, or whatever you may please to call it, it should be on the north of your dwelling house, the better to avoid the deleterious effects of the gases arising from the decomposition of the various matter you may make available in forming manure. Your stables and cow-sheds should be on the highest elevation in your lot; your dung pit on the lowest side, and formed in the following manner:—Mark off in a straight line, (or an elliptic form will answer if the fence around your lot is in that form,) the size you intend for your pit. Strip off all the soil until you come to a solid foundation, say two feet deep at the lowest side, gradually less until you arrive at the surface or upper side of the pit, and form a bank with the soil you take off on the lowest side, close to your lot fence; then form side wings from this line, diverging in width from a right angle about thirty degrees, so as to embrace all the wash or moisture that may incline from your stables and cow-sheds, and endeavor to make this the receptacle of every thing that comes off your farm that can be converted into manure First, all noxious weeds about your garden and lots during the summer; next keep your stables well littered with leaves or straw, and, in the fall of the year, keep your lot well covered with corn and cotton stalks, and when tolerably well trodden, say every two or three weeks, select a rainy day and clean out your stables and cow-sheds, and rake up your lot, and with a wheelbarrow deposite all in the pit. Then litter your stables well with refuse straw, and strew your lot twelve inches deep with all and every thing that can be converted into manure. Follow up this process, and leave the side of the pit nearest your stables gently sloping, so that by laying a plank there you will be enabled to wheel up your manure after the pit has filled to a considerable height.

Your stable manure and moisture becoming amalgamated with the mass in the pit, which, by its well known heating and fermenting qualities, will soon decompose the mass into a solid, well rotted manure; and, by pursuing this method, on the March following you will have every thing that came of your farm the previous year, in a proper form to return to it again, and have the good reflection of carrying out the principles of natural justice towards Mother Earth, and you will meet your reward in her increased fertility.

The scientific may object to this process of forming a dung pit, as calculated to destroy or let the ammonia escape; but this can be obviated by mixing a layer of muck, rotten wood, coal dust or marl, or common soil will answer in a great degree. Thus, whenever you add any thing to your dung pit, cart in a few loads of either of the above absorbents, which will sufficiently fix and retain the ammonia.

The smallest farm may with care, in this manner, manure ten acres of land well; and if he will devote his spare time and wet days to composting in his woods, where nature has given him ample material in rotten logs and leaves, also the vegetable mould which has accumulated in the corners of his fences, he may manure and give a good dressing to ten acres more, and that with less labor than would be expended in clearing five acres of knobby land, (which is all that a goodly number of farmers have now to clear.)

If from these rambling views, any of your readers may glean a single hint, and improve the same, the aim of the writer is accomplished; and if you think you can present them to your readers in a form worthy of your valuable paper, I may be induced to trouble you again at some future day.

Yours, with respect.

WOODVILLE.

HINTS FOR HARD TIMES.—Rise early in the morning, be diligent during the day, in attending to our business, and not worry ourselves with our neighbor's concerns.

Give encouragement to home industry, and in all give the preference to American manufactures over foreign in every case, when they are equally good.

Instead of following the fashions of Europeans, let a spirit of independence be cultivated, and decide for ourselves how our coats, boots and hats shall be made.

Keep out of the streets, unless business calls us to transact that which we cannot do in our shops or dwellings.

By all means keep away from drinking and gambling houses.

When we buy an article of clothing, study commendable economy, at the same time get a good article, and wear it out regardless of any change of fashion—fashion is a great tyrant and men are fools to be slaves to it.

Stay home at nights, improve yourselves by reading, writing or instructive conversation, and retire to your beds at an early hour.

Be kind to your relations, obliging to your friends and charitable to all.—*Maine Cult.*

CURE FOR THE RED-WATER IN CATTLE.—Take a mixture of equal parts of oleum philosophorum, oleum aspte and oleum terebinthum, and put sixty to seventy drops in half a quart of lukewarm water for a middle-sized cow, and from thirty to fifty for a calf. If it does not cure in twelve hours, repeat the dose.

CHOKED CATTLE.—My mode of giving relief to choked cattle is, to let them have *a good pinch of snuff*. They will sneeze and throw up any that is too large to pass down. Will you try it?

AGRICULTURAL CHEMISTRY

CARBON—ITS PROPERTIES AND RELATIONS TO VEGETABLE LIFE.

Carbon is the name given by chemists to the substance of wood charcoal in its purest form. When wood is distilled in close vessels, or burned in heaps covered over, so as to prevent the free access of air, wood charcoal is left behind. When this process is well performed, the charcoal consists of carbon with a slight admixture only of earthy and saline matters, which remain behind on burning the charcoal in the air.

Heated in the air, charcoal burns with little air, and, with the exception of the ash which is left, entirely disappears. It is converted into a kind of air known among chemists by the name of carbonic acid, which ascends as it is formed and mingles with the atmosphere.

Charcoal is light and porous, and floats upon water, but plumbago or black lead and the diamond, which are only other forms of carbon, are heavy and dense. The former is 2¼ and the latter 3½ times heavier than water. The diamond is the purest form of carbon, and at a high temperature it burns in the air or in oxygen gas, and like charcoal, disappears in the state of carbonic acid gas.

Of this carbon, all vegetable substances contain a very large portion. It forms from 40 to 50 per cent, by weight, of all the parts of plants which are cultivated for the food of animals or of man, that is, of these plants in their dried state. In the economy of nature, therefore, it performs a most important part.

The light porous charcoals obtained from wood, (especially from the willow, the pine and the box,) and from animal substances, possess several interesting properties, which are of practical application in the art of culture. 1. They have the power of absorbing in large quantity into their pores, the gaseous substances and vapors which exist in the atmosphere;* and on this property, as I shall explain hereafter, the use of charcoal powder as a manure probably in some measure depends. 2. They also separate from water and decayed animal matters or coloring substances which it may hold in solution; hence its use in filterers for purifying and sweetening impure river or spring waters, or for clarifying syrups and oils. This action is so powerful that port wine is rendered perfectly colorless by filtering through a well prepared charcoal.

In or upon the soil charcoal for a time will act in the same manner, will absorb from the air moisture and gaseous substances, and from the rain and from flowing waters, organized matters of various kinds, any of which it will be in a condition to yield to the plants which grow around it, when they are such as are likely to contribute to their growth. 3. They have the property also of absorbing disagreeable odors in a very remarkable manner. Hence animal food keeps longer sweet when placed in contact with charcoal—hence also vegetable substances containing much water, such as potatoes, are completely preserved by the aid of a quantity of charcoal—and hence the refuse charcoal of the sugar refiners is found to deprive night soil of its disagreeable odor, and to convert it into a dry and portable manure. 4. They exhibit also the still more singular property of extracting from water a portion of the saline substances they may happen to hold in solution, and thus allowing it to escape in a less impure form. The decayed (half carbonized) roots of grass, which have been long subjected to irrigation, may act in one or all these ways on the more or less impure waters by which they are irrigated—and thus gradually arrest and collect the materials which are fitted to promote the growth of the coming crop.

*Thus of ammonia they absorb 95 times their own bulk, of sulphuretted hydrogen 55 times, of oxygen 9 times, of hydrogen nearly twice their own bulk, and of aqueous vapor so much as to increase their weight from 10 to 20 per cent.

That life is long which answers life's great ends.—*Young.*

PLANTERS' CLUB OF HANCOCK.

The Annual Fair of this Club will take place at Sparta, on Friday, 3d November, 1843, on which day all crops, stock, and articles that may be offered for premiums or honors, will be examined by the committees appointed for that purpose; and on the next day, Saturday, the committee will report, the public exhibition of stock and other articles will be made, and an address be delivered before the Club. Premiums awarded on the following articles:

For the best acre of Corn.....$5 00
" 2d best do.....3 00
" 3d, 4th and 5th do—Honors.

For the best acre of Wheat.....5 00
" 2d best do.....3 00
" 3d, 4th and 5th do—Honors.

For the best acre of Oats.....5 00
" 2d best do.....3 00
" 3d, 4th and 5th do.—Honors.

For the best acre of Sweet Potatoes.....5 00
" 2d best do.....3 00
" 3d, 4th and 5th do—Honors.

For the best acre of Turneps.....5 00
" 2d best do.....3 00
" 3d, 4th and 5th do—Honors.

For the best acre of Cotton.....5 00
" 2d best do.....3 00
" 3d, 4th and 5th do—Honors.

Competitors for premiums on crops will be required to give the *modus operandi* of culture.

For the best Stallion of four years and upwards.....5 00
" 2d best do.....3 00
" 3d, 4th and 5th do—Honors.

For the best 3 year old Colt or Filly.....3 00
" 2d best do.....2 00
" 3d, 4th and 5th do—Honors.

For the best 2 year old Colt or Filly.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best sucking Colt or Filly.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best brood Mare, with or without a Colt.....5 00
" 2d best do do.....2 00
" 3d, 4th and 5th do—Honors.

For the best Bull.....3 00
" 2d best do.....2 00
" 3d, 4th and 5th do—Honors.

For the best 2 year old Bull.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best Milch Cow.....3 00
" 2d best do.....2 00
" 3d, 4th and 5th do—Honors.

For the best 2 year old Heifer.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best Tup.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best Ewe.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best Boar.....3 00
" 2d best do.....2 00
" 3d, 4th and 5th do—Honors.

For the best Sow.....3 00
" 2d best do.....2 00
" 3d, 4th and 5th do—Honors.

For the heaviest fat Hog, from one to two years old, in proportion to age..2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the heaviest Pig, agreeably to age, from 6 to 12 months old.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best piece, of 10 yards, Homespun, for gentleman's wear.....3 00
" 2d best do.....2 00
" 3d, 4th and 5th do—Honors.

For the best Counterpane,.....3 00
" 2d best do.....2 00
" 3d, 4th and 5th do—Honors.

For the best piece of 10 yards of Domestic Silk.....5 00
" 2d best do.....3 00
" 3d, 4th and 5th do—Honors.

For the best article of Negro Clothing....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

For the best article of Negro Blanketing—Cotton or Wool.....2 00
" 2d best do.....1 00
" 3d, 4th and 5th do—Honors.

The Club will award liberal premiums and honors on all articles which may be manufactured by ladies and offered for exhibition—such as needle-worked capes, caps, work-pockets, stockings, gloves, &c.; in fact every article that may be sent by them.

TUTTLE H. AUDAS, Sec'y.

Sparta, Ga.

OVERTRADING.

We have seldom, says the Central New-York Farmer, read a more graphic description of the troubles of a man of business, than the one annexed. And yet although all this is true, and probably falls far short of the reality, often our farmers are preparing their sons to rush into the vortex of mercantile life, and will soon be called upon to witness in their history the same results, which when too late to remedy, they will most surely lament. We would urge them now to pause—and prepare their sons not for the hazards and trials of mercantile life—but for the labor, the joys and happiness of agricultural pursuits.

"OVERTRADING.—What a lesson the grasping, anxious overtrading man of business receives during a panic! His visions of wealth, the dream and hope of his life, the calculations of his brain for years, vanish—all die in a single day! The glossy bubble bursts and its contents fly into thin air. When will men learn wisdom, and be content to do business within their means? How much happier would a man's life pass, could he divest himself of that greedy craving after riches, and be satisfied with making money moderately, pay more attention to his health and comfort, the virtues of society, and enjoy the blessings within the reach of every one in this happy land!

"He who contracts his swelling sail,
Eludes the fury of the gale."

What a life of abject slavery do the generality of our merchants lead! Dependent on their credit, dependent on the banks, dependent on their customers, dependent on their friends, what happiness do they know? None. Up early—they scarcely take time to swallow their breakfasts, and hurry to their stores, where their minds are immediately engaged deep in business, and they are subject to the constant disappointment and harrassing results of an over extensive trade on small means. They have no time through the day to enjoy peacefully the dinner hours, but, with their brains full of calculations, hasten through it, and again to business, as if their very lives and souls depended on the making of money. When evening comes, tired and worn out, perplexed and weary, they seek their homes, not to partake of recreation, and the comforts of social intercourse with their families, but to a feverish, sleepless night's rest, and in the morning to a repetition of the scenes of aggrandisement and ambition which every succeeding day brings forth.

LIGHTWOOD FROM OLD FIELD PINES.—Mr. J. H. Fugua, in writing for the Southern Planter, makes a few remarks on old field pines, the correctness of which we hope some of our correspondents will put to the test of actual experiment and furnish us with the result.

He remarks, "I consider a grove of such pines exceedingly valuable for garden posts, or posts of any kind; if properly prepared, they will last as long as locust or any other timber. My mode of treatment is as follows: I take a drawing knife and draw off the bark as the tree stands, as high up as I want to use it: in this situation, the tree, which will not die, remains a twelvemonth, when, in consequence of the sun having drawn the rosin to the surface, it will become a solid bulk of lightwood, and will be ready for use."

Planter.

PLANTING LARGE POTATOES.—We have been of the opinion, that if large potatoes were planted instead of *slips*, a much finer crop would be made, and we requested a friend, who raised unusually large potatoes to try the experiment last year, of planting both kinds—the very large and the slips. The following is a letter received from him on the subject.—*Planter.*

DEAR SIR—I promised you the result of an experiment in planting the full grown and largest size sweet potato, instead of the smallest size, such as are usually planted. As you are aware, I alternately planted one row of large and one of very small potatoes. In harvesting I could not perceive any advantage whatever from the large over the small seed. This result was contrary to my expectation, particularly as there was a marked difference in the vine, during the early part of the summer, those from the largest seed appearing much more vigorous

AUGUSTA MARKET.

TUESDAY P. M., April 25.

Cotton—Since our report of last Tuesday, the market remained in a very inactive, quiet state, until after the receipt, on Sunday night, of the accounts from Liverpool to the 4th instant, by the Britannia, at Boston, which were deemed more favorable, and quite an active business engaged dealers on Monday, at an advance of ¼ to ⅜ of a cent, but to-day that feeling is subsiding, and the market seems to be quietly dropping back to its former position, though it has not yet reached that point.

Exchange is at par on all points. Central Bank, Alabama notes, and State 6 ℔ cent Bonds have undergone no change since our last report.

CONTENTS OF THIS NUMBER.

	PAGE.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first inscrtion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., MAY 3, 1843. No. 9.

MR. FOOTE'S PRIZE ESSAY.

[Continued from page 58.]

MANAGEMENT OF OUR STABLES.

From facts like the above, we should be quick to gather lessons of wisdom; not lessons of knowledge merely, (for they may be profitless,) but lessons of that practical wisdom, which not only comprehends and appreciates what is good, but employs the best means of its attainment.—Let our *stables* receive a just share of attention: let the ground beneath them be shaped as to conduct the urine which falls upon it, directly to the common reservoir in the yard; or let it be excavated in a proper form and supplied with suitable absorbents; or let the floors be made tight, so that the urine can be taken up by the litter, or conveyed by gutters to the yard, and there can be no question that at least one-third will be annually added to the value of our stock manures.

Where any of the improved machines for that purpose are in use, the expense of *cutting* the straw intended for litter will be more than repaid, by the greater ease with which the floors may be cleaned, especially in winter, by the greater amount of liquid it will absorb, and by the greater facility and evenness with which the manure may be spread in the spring. Dry powdered muck and loam, stored under cover for the purpose, may also be highly recommended for free use in the stables, as being well adapted to prevent the waste of the liquids there, and also to the escape of the juices and gases from the heaps as they are formed without. And last, not least, an occasional sprinkling of plaster over floors will not only preserve such salts as would otherwise be lost by exhalation, but at the same time greatly contribute to the sweetness of the stables.

MERITS OF THIS SYSTEM.

It is not imagined that the system now indicated for the preservation of our barn yard manures is a perfect one, securing all advantages desirable to be secured. It does not wholly protect the manures from the wasting action of the atmosphere, nor from liability to loss by infiltration and drainage. But, perhaps, considering the universality of its application, and the comparative ease and cheapness with which it may be adopted, it is the best that can be recommended for general practice. In situations where it is practicable, additional advantages may be unquestionably secured by the use of a *barn cellar*, into which any or all of the manures of the establishment may be thrown, with suitable absorbants, and the whole wrought together into the richest of all composts by the voluntary labors of the swine. No doubt farmers will find their account also in *housing* their manures as much as possible, since by being thus protected, their most valuable portions (their juices and salts) will be preserved to a much greater extent than it is possible for them to be in the open air.

COMPARATIVE VALUE OF MANURE.

The barnyard being the common receptacle of the excrements of the horse, the cow and the sheep, and the great object having been, thus far, to point out the best mode of saving the *whole* of them, the *comparative value* of these different substances has passed unnoticed. In order, however, that the farmer may direct his labors for the preservation of his manures to the greatest profit, he should certainly have the benefit of all known facts on this point.

"The quantity of vegetable and animal matter in horse dung is considerably larger than in cow dung. It is as 27 to 14, or nearly double; and of course the quantity of nitrogen which it is capable of yielding is nearly double that of cow dung. Sheep dung is similar to horse dung, but contains a greater quantity of vegetable matter in a soluble state. It is also richer in salts; and the quantity of nitrogen which it is capable of yielding is greater than in either of the preceding substances. Hog manure contains still larger quantities of soluble matter, and is capable of yielding a large quantity of nitrogen in the form of ammonia. It ranks next in value to night soil, which has ever been celebrated as the most valuable substances used for manure."—*Gray's Agriculture, p.* 286.

"Experiments undertaken by order of the Saxon and Prussian authorities, varied in every form, and continued for a long period, prove that if a soil without manure yield a crop of three for one sown, then the same land dressed with cow dung yields seven for one sown—with horse dung ten for one sown—with human manure fourteen for one sown."—*Dana, p.* 143.

THE PIGGERY.

Still greater care will here be requisite to 'see that the commonwealth receives no detriment,' inasmuch as the treasures at stake are of higher value, and from two circumstances more liable to waste, viz: there being a greater proportion of liquid excrements, and the solid portions being more exposed, from the fact of their being constantly upturned by the rooting of the swine, and thus presenting every hour in the day fresh surfaces to the action of the sun and winds.

The former of these circumstances will be judiciously met by supplying the pens with an abundance of straw, leaves, saw dust and the like; the latter by furnishing the yard with an occasional load of muck, and almost any quantity of weeds, pea and buckwheat straw, potato vines, &c.—all of which will be rapidly converted into the most efficient supports of vegetable life.

It is suggested whether it would not be an improvement on the present system, were the yard and pen but one enclosure, consisting of an open area under cover, (with floors for eating only,) where the same use might be made of muck and litter as at present, and the whole completely shielded from the atmosphere.

THE PRIVY VAULT.

This, in proportion to the volume of its contents, should command a greater share of our solicitude than any other of the depositories of the farm manures. Consider simply the *nature of the food* from which the substances under consideration result, we might well suppose them to possess a superior efficacy in promoting the growth of the finer plants and grains; a supposition which agricultural chemistry unites with all experience in fully justifying. So far, therefore, as the simple preservation of manure is concerned, it is doubtless from this quarter that the farmer can derive the greatest profit at the least expense.

Let the vault, then, (constructed with a due regard to convenience, as well as to the exclusion of air and moisture,) be carefully supplied at proper intervals, with powdered charcoal alone or with dry powdered muck and gypsum, (the best of all substances for this purpose, but for which cut-straw, surface soil, ashes and old lime may be substituted,) and the object will be fully accomplished. The liquid portions will be absorbed, and the volatile productions converted into fixed salts; the whole mass will become inodorous and inoffensive, (no small advantage to the family as well as to the farm,) and a goodly quantity of the richest of manures will be prepared for convenient application to the cultivated crops.

VALUE OF HUMAN EXCREMENTS.

Deeply impressed ourselves with the value of these excrements, and deeming it of no small importance that a general interest should be awakened in relation to them, we cannot forbear from presenting our farmers with one or two pertinent quotations.

"In respect to the quantity of nitrogen contained in excrements; 100 parts of the urine of a healthy man are equal to 1300 of the fresh dung of a horse, and to 600 parts of those of a cow. Hence it is evident that it would be of much importance to agriculture if none of the human urine were lost. The powerful effects of urine as a manure are well known in Flanders, but they are considered invaluable by the Chinese, who are the oldest agricultural people we know. Indeed, so much value is attached to the influence of human excrements, that laws of the state forbid that any of them should be thrown away, and reservoirs are placed in every house, in which they are collected with the greatest care. No other kind of manure is used in their cornfields. The agriculture of this country is the most perfect in the world."

"If we admit that the liquid and solid excrements of a man amount on an average to 1¼lbs. daily, (5-4 lbs. urine and ¼ lb. fæces,) and that both taken together yield 3 per cent nitrogen, then in one year they will amount to 547 lbs., which contain 16½ lbs. nitrogen, a quantity sufficient to yield the nitrogen of 800 lbs. of wheat, rye or oats, or of 900 lbs. of barly. This is much more than is necessary to add to an acre of land, in order to obtain, with the assistance of the nitrogen absorbed from the atmosphere, the richest possible crop every year. Every town and farm might thus supply itself with the manure, which besides containing the most nitrogen, contains also the most phosphates; and if an alternation of the crops were adopted, they would be most abundant. By using at the same time, bones and lixivated ashes of wood, the excrements of animals might be dispensed with.—*Liebig p.* 184.

"In Belgium, which has been the cradle of enlightened agriculture, and where good modes of cultivation are continued and constantly improved, they make astonishing use of this kind of manure. So great a value do the Flemings attach to it, that the cities set a high rate upon the privilege of disposing of the cleansing of their privies, and there are, in each one of them, sworn officers for the assistance of those who wish to make purchases."

"We shall find great difficulty in bringing this branch of industry to the same degree of perfection amongst us, that it has arrived at in Belgium, because *our farmers do not realize its importance;* and have a repugnance to employ-

ing this kind of manure. But could they collect carefully all these matters, mix them with lime, plaster or gravel, till the odor was dispelled, and then carry the whole upon the fields!"

"Already, in most of our great cities, the contents of the privies are used for forming poudrette; this pulverulent product is sought for by our agriculturists, who acknowledge its good effects, let us hope that, becoming more enlightened, they will employ the fecal matter itself, as being more rich in nutritive principles, and abounding equally in salts; they can easily govern and moderate the too powerful action of this, by fermentation, or what is still better, by mixing it with plaster, earth, and other absorbents, to correct the odor.—*Chaptal, p.* 62.

PURE ANIMAL MATTER.

All animal matter, such as the carcases of dead animals, unmerchantable fish, the refuse of the slaughter house, the relics of the kitchen and the waste of the tan yard, the shoe shop, the carding mill, the comb, glue, soap and woollen cloth manufactories, &c.—by being seasonably gathered up and either incorporated with the barn yard manures, combined with compost materials, or buried directly in the soil, will prove the most efficient aids in promoting fertility. "The carcass of a dead horse," says Lord Meadowbank, "which is suffered to pollute the air with its effluvia, has been happily employed in decomposing 20 tons of peat earth, and transforming it into the most valuable manure."

In illustration of the value of numerous refuse matters commonly accounted "good-for-nothing," and thrown away, it may here be stated that the finest crop of eight-rowed corn inspected by the Agricultural Committee of Berkshire, the present year, owed its superiority, in their opinion, to the employment of a compost manure, in which the principle ingredient was *woollen flocks*. The soil was thin, consisting of exceedingly coarse gravel; yet the growth was luxuriant and the ears well filled, perhaps beyond comparison for the present year."

PURE VEGETABLE MATTER.

This may include straw, leaves, vines, &c., and green and ripened crops ploughed under to improve the soil; but the consideration of this topic being unnecessary in the present connection, it will be reserved for a future paragraph, under the second branch of our general subject, viz:

THE APPLICATION OF MANURES.

In order to the judicious application of our manures, it is obviously necessary that we have regard to certain characters and conditions of soil; as the proportions of its inorganic constituents, the amount of its organic materials, and its relations to temperature and to moisture.

INORGANIC CONSTITUENTS OF SOIL.

By the inorganic constituents of soil are meant those purely *earthy* substances which form the *basis*, and chiefly determine the *texture* of all soils, but which of themselves, whether in a combined or separate state, are wholly incapable of vegetation. Such are gravel, sand and clay, (as also lime,) which constitutes the basis of the great majority of all our soils.

CONSTITUTIONAL CHARACTER OF SOIL.

When either gravel or sand predominates in the constitution of a soil, it is termed silicious, from silica, the common name of gravel and sand. When clay predominates, it is denominated argillaceous aluminous, from argil and aluminia, both of which signify clay in a pure state. If lime be a principle constituent, it is called calcareous, for calx, signifying chalk, which is only a certain modification of lime.

PHYSICAL CONDITIONS OF SOILS.

The different proportions in which the inorganic constituents enter into the composition of any soil, will also chiefly determine its physical condition; i. e. it will be light or heavy, (more properly, loose and compact,) wet or dry, warm or cold, in proportion as it consists chiefly of gravel and sand, or mostly of clay.

ORGANIC CONSTITUENTS OF SOIL.

By the organic constituents of soil are meant those vegetable and animal substances which help to compose the soil to a certain depth, which exert a considerable influence also upon its texture, and upon which vegetation is extirely dependent for its subsistence. In scientific works on agriculture, this portion of the soil is usually treated of under the name of *geine, humus or vegetable mould;* and embraces every thing in the soil capable of decomposition, and thus becoming the food of plants.

OBJECT OF THE APPLICATION OF MANURES.

To increase this organic portion of the soil, is the great object of the application of manures. It should not, however, for a moment be imagined that the simple augmentation of the proportion of organic matter will insure fertility, since very much depends upon the state as well as the quantity of this matter in the soil. It is upon these two circumstances taken in connection, that the farmer is wholly dependent for success in all his agricultural operations.

CERTAIN CONDITIONS OF THE SOIL PRE-REQUISITE.

In illustration of what is meant by the dependence of fertility on the state of the geine in the soil, it may be observed, that manure applied to either gravel or clay in a pure state, might as well be applied to the surface of an equatorial desert, a pool of water, or an island of ice; the former (gravel,) being destitute of that quality of compactness which is necessary to prevent the salts and juices of the manure from escaping at once into the earth, or air, and to retain a sufficient degree of moisture for the purposes of vegetable life; and the latter wanting that opposite quality of prosity which is requisite for the escape of that superabundance of moisture, which by its own presence, and the exclusion from the soil of the other atmospheric agents, would prove equally fatal to all the processes of vegetation.

The proposition, therefore, must approve itself to every intelligent farmer, that the fertility of the soil depends not only on the *quantity* of geine in the soil, but also on the *state* of that geine as affected by its relations to the inorganic constituents. Hence the importance to the agriculturalist of making himself acquainted with the nature of the soil in general, and of his own soil in particular, that he may husband to advantage his means of fertilization, and not expend his strength in labors that will in the end prove fruitless.

CONSTITUTION OF THE BEST ARABLE SOIL.

The proportions in which chemical analysis has ascertained the different constituents of the most productive soils to exist, are about as follows: silica) gravel or sand) 60 parts to 100, alumnia (clay) 16 parts, lime 3 parts, oxide of iron and manganese 7 parts, geine (organic matter capable of becoming the food of plants,) 9 parts, potash 3 parts, soda 1 part, magnesia 1 part.

Says Chaptal: "From the results of analysis we find, that in the best earths there is a large quantity of gravel, which renders the soil light and easily worked, facilitates the passing off of superabundant rains. In consulting analysis of less fertile soils, we find that their fertility diminishes in proportion as one or the other of the three principal earths, (silicia, alumnia and lime predominates; and that it becomes almost nothing in those which possess the properties of but one. The mixture of earth then is necessary to the formation of a productive soil; and their proportion can be varied only according to the nature of the climate, and the kind of plants to be cultivated. Silicious and calcareous earths may form a larger proportion of the soil in moist, than in dry countries, and alumina may, in its form, predominate in those lands which, from their declivity, suffer the water to flow off freely; but a mixture of the three earths can alone form a good soil, and too great a disparity in their proportions materially affects the character of it."—p. 26.

STARTING POINT OF IMPROVEMENT.

Here then, is evidently the starting point, from which the farmer that would run the race of improvement, must calculate his "latitude and departure." From this post of observation must he survey the sphere of his labors, carefully noting the several ingredients of his soils, and the different proportions of their several combinations, as well as their different conditions; and thus will he be qualified to enter intelligently on the execution of any scheme relating to their improvement. If a careful observer, he will early make the important discoveries.

1. That an excess of silicious or calcarious substances, by rendering the soil too porous, occasions the speedy disappearance of his manures, exposes his crops to suffer from droughts and frequently disappoints his hopes of a harvest, and frustrates all his efforts at successful cultivation.

2. That an excess of argillaceous matter, by rendering his soil too compact, obstructs the passage of the surface waters that rest upon it in spring, refuses admittance through its indurated surface to the fertilizing dews of summer, excludes the healthful influences of the sun and air from the roots of his plants at every period, receives with indifference whatever manures he puts upon it, and renders all his labors upon it, to a great extent, abortive.

3. That a certain admixture of the different earths composes a soil sufficiently light and warm, meeting without detriment the ever varying states of the atmosphere, affording a ready passage to the rains in wet weather, and to the dews in dry, appropriating largely to his crops the beneficial influence of the sun and air, making the most of every particle of manure received, and amply compensating him for all the labor he expends upon it.

SOILS TOO COMPACT OR POROUS IMPROVED BY ADMIXTION.

Having made the above discoveries, the resolute *improver* of the soil will come at once to the conclusion, that which the hand of nature has left unfinished it is for *his* to complete; and setting himself at work in imitation of the *pattern* she has furnished him, will, by a due adjustment of the different ingredients of his several soils, bring up, at length, the poorest of his lands quite to the standard of the best.

He will not, however, find it advisable, in most instances, to effect this adjustment directly, i. e. by carting soil from one field to another for the purpose of admixture; but, rather to cart it first to the cattle yard to be blended with a portion of solid and liquid manure, and thence convey it to the localities selected for improvement.

This practice has been followed to some extent, by the writer, and with the most distinguished success. Indeed, so marked have been the beneficial results of this system as to leave upon his mind the full impression, that for a light, silicious soil, two loads of argillaceous earth well mixed in the cattle yard with one of manure, are of more actual value than would be three equal loads of clear stable manure.—For a heavy, aluminous soil, a similar treatment with gravelly or sandy loam combined with manure will prove equally beneficial.

SOILS IMPROVED BY DRAINING.

On wet lands manure should never be applied at all. Let such lands be thoroughly drained, and in most cases it will be found that no manure is needed; the soil being already supplied with a sufficiency of vegetable matter, which, having been kept in an insoluble state by an excess of moisture, will, under more favorable circumstances, become decomposed, and furnish abundant support to vegetation. But when it is needful that manure should be applied to lands of this description, thorough draining should, in every case, precede the application, and then the expense will be remunerated.

[To be continued.]

CONSUMPTION OF COTTON.

A series of articles in the course of publication in the Boston Advertiser, addressed to the cotton manufacturers of Massachusetts, are replete with interest to that branch of industry, and contain much that is useful to the merchant and planter in reference to this great staple.—Without concurring in the views of the writer in regard to prices, which it is considered "will decline below existing rates," and for which various reasons are assigned—most of them however, contingencies, which may or may not happen, we extract the following remarks upon the consumption of cotton in Europe:

"If the gross products of the nations of Europe were as great as in this country—taxation as inconsiderable, and property as equally distributed among the masses of the people as with us—why the consumption of cotton in Europe, instead of being limited as it now is, to about 1,800,000 bales, would be extended to 4,166,666 bales. The truth of that assertion may be seen by taking the consumption of this country at 260,000 or 270,000 bales—which perhaps is as much as we now require, and adding to that the consumption of imported cotton goods to the extent of $6,000,000 or $8,000,000—and thus allowing the aggregate consumption 300,000 bales.

The population of Europe is about 250,000,000. If then our population of 18,000,000 consume 300,000 bales of cotton, it follows that a population of 250,000,000, having an equal consuming ability, would consume 4,166,666 bales.

The consumption of cotton in Europe is rapidly increasing under the increasing industry, skill, economy, and the general prosperity incident to a long continued peace. The average of our crops in 1820 and 1821, was 136,000,000 pounds—and Mr. Clay, in one of his speeches in favor of converting cotton growers into the manufacturers of cotton and of other raw materials, gave it as his opinion on which he founded his arguments, that the world was too full of cotton—the consumption having reached its *maximum*.

"We have reached the *maximum of foreign demand* for our three great staples, cotton, tobacco, flour," &c. Thus said Mr. Clay in 1820, when our crops of that staple averaged for 1820 and 1821, 137,000,000 pounds. The coming crop will not fall short, as is generally supposed, of 940,000,000 pounds, and may exceed *one thousand millions of pounds*.

It is true, as we have contended, that production of cotton is in advance of its consumption, but the extreme low prices to which it will probably fall if the crop is as large as estimated—will first discourage cultivation to some extent in Asia, as far as European consumption is relied upon. Secondly, the fall in the value of so important and useful a staple, to prices far below those of any other manufacturing materials which can be brought into competition with it, cannot fail to augment its consumption to a great extent. That, however, will not take place in season to sustain existing prices of the present crop, because an increased consumption greatly beyond what has ever before been experienced, will still leave a heavy surplus at the close of this year, *far beyond that of any former period*.

As to a "maximum of consumption," it is an absurdity—since it implies that mankind are stationary, not only in their wants and in their increasing means of gratifying them, but in numbers also—whereas, since the fall of Bonaparte, and the return to a general peace, the population of most of the nations of Europe has increased in a greater ratio than at any anterior period.

Again, the means of consuming cotton and of many other products, which, in a state of war, are beyond the consuming ability of European population, have been increased two or three fold, and the longer the general peace is maintained, the greater will be the ratio of consuming ability, not only of cotton, but of all the great staples of commerce.—*Mobile Register*.

THE COTTON TRADE.

It will be seen by the quotations of cotton in the various prices current of the day, that the range of prices is from 4¼ to 6¼ or 8 cents, embracing the extreme limits. It is the first time in the history of this important staple that the price has ever touched so low a point. During the embargo or non-intercourse of 1808 and 1809, and the war of 1812 and 1813, the prices never went down within one or two cents as low as it is at the present period. The following table, taken from Hunt's valuable magazine, exhibits the value and price for the last 21 years.

Years.	*Millions of lbs.*	*Av. price.*	*Value.*
1820	160	17 cts.	27,200,000
1821	180	16	28,800,000
1822	210	16½	34,650,000
1823	185	11	20,350,000
1824	215	15	32,250,000
1825	255	21	53,550,000
1826	350	11	38,500,000
Tot'l 7 yrs.	1555	15½	234,675,000
1827	270	9½	27,700,000
1828	325	10¼	40,625,000
1829	365	10	36,500,000
1830	350	10	35,000,000
1831	385	9¼	35,612,000
1832	390	10	39,000,000
1833	445	11	48,950,000
Tot'l 7 yrs.	2530	10	263,537,000
1834	460	13	59,900,000
1835	416	16½	68,940,000
1836	455	15½	67,862,500
1837	485	15½	73,962,500
1838	525	10¼	53,812,500
1839	566	14	79,240,000
1840	880	9½	83,600,000
Tot'l 7 yrs.	3777	13⅛	487,117,500

This is a highly interesting table. The growth since 1840 is not given, but that of 1842, it is believed, will reach two and a quarter millions of bales.

The increased growth of cotton, and the rapid reduction in price, are subjects of much speculation. If the cotton planters of the South could realize the average prices, ending 1840, viz: 13⅛ cents, what an immense difference there would be in the value of the crop. But reduced as it is to 6 or 6¼ cents, the difference is truly great. The fall however must, in the end, be less injurious to our Southern planters, than to the people of any other country, The upland cotton of this country is a favorite with the manufacturers, as they prefer it to any other short staple, owing to its working more kindly in the machinery. Its low price will therefore go far to drive out of the European markets every other description.

The low price of the raw material both here and in Europe, will also affect the price of the manufactured article. Domestic goods, which have been selling at very low prices, will be afforded still lower. It is also understood that the manufacturers in this country have very light stocks of the raw material on hand, consequently they will not be sufferers by the late fall in the price of this article. The export of domestic goods is greatly increasing. The export of cotton from this country to India, owing to low prices, is also becoming very considerable.—*N. Y. Express*.

Book Farming.—Show me a thrifty, practical and experimental farmer, and I will show you a man who reads works on agriculture, or who borrows his hints from a neighbor who takes agricultural papers.

Show me a farmer whose fences are going to decay; whose half starved cattle are strolling over a brush field; and I will show you a man who, if he is not on the retrogade track, takes too little interest in agriculture to patronize an agricultural paper.—*Farmers' Cabinet*.

EXPERIMENT WITH SALT AS A MANURE FOR WHEAT.

In Johnson's Agricultural Chemistry, already mentioned, are contained some highly important experiments on wheat fields, by Wm. Fleming. Mr. F. gives the result of eight different kinds of manure on the eighth of a Scotch acre of wheat. The two most important are, Nitrate of Soda, 80 lbs., Rape Dust 5 cwt. to the acre, which produced 240 lbs. of wheat, weighing 62¼ lbs per bushel, on one eighth of an acre.

Common salt, 160 lbs. to the acre, produced 219 lbs. of wheat, weighing 62¼ lbs. per bushel, on the same quantity of ground. While the same measure of land, without any manure, produced only 90 lbs. of wheat, weighing 61 lbs. to a bushel. The salt is therefore the most economical and productive manure used by Mr. F. in his course of experiments.

Five bushels of Liverpool salt to the acre is said to produce great effect on any crops, either of grass, grain or roots. More than six have been found to be injurious sometimes. The use of salt as a manure was early known by the Romans and other nations of antiquity, but has been little understood or practised in modern times. It is somewhat extraordinary that this important item in the cultivation of the earth should have gone into disuse on the sea coast especially, where the inexhaustible fountains of the deep are continually dashing their briny billows at the feet of the cultivator. But modern experience has demonstrated its usefulness, whenever it has been tried.

It is also destructive to insects, the greatest enemies of the vegetable kingdom; and if it had no power as a manure, this alone makes it more valuable to the world, than all the preventatives which the ingenuity of man has been able to discover against the innumerable hosts of these depredators, with which the earth is infested.

A thin sprinkling of green sea-weed, salt hay, sedges, or any other marine vegetable, on pasture, old meadows, or plowed land, contains sufficient salt to produce most suprising effects, if spread so sparse as to let the grass grow freely through it, and to admit the rays of the sun to the earth. Like every other powerful, concentrated manure, a *little too much* destroys vegetation for a time.—*Conn. Farmer's Gazette*.

SIX REASONS FOR PLANTING AN ORCHARD.

BY EDSON HARKNESS.

1st. Would you leave an inheritance to your children?—plant an orchard. No other investment of money and labor will, in the long run, pay so well.

2d. Would you make home pleasant—the abode of the social virtues?—plant an orchard. Nothing better promotes among neighbors a feeling of kindness and good will, than a treat of good fruit, often repeated.

3d. Would you remove from your children the strongest temptation to steal?—plant an orchard. If children cannot obtain fruit at home, they are very apt to steal it; and when they have learned to steal fruit, they are in a fair way to learn to steal horses.

4th. Would you cultivate a constant feeling of thankfulness towards the great Giver of all good?—plant an orchard. By having constantly before you one of the greatest blessings given to man, you must be hardened indeed if you are not influenced by a spirit of humility and thankfulness.

5th. Would you have your children love their home—respect their parents while living, and venerate their memory when dead—in all their wanderings look back upon the home of their youth as a sacred spot—an oasis in the great wilderness of the world?—then plant an orchard.

6th. In short, if you wish to avail yourself of the blessings of a bountiful Providence, which are within your reach, you must plant an orchard. And when you do it, see that you plant good fruit. Don't plant crab apple trees, nor wild plumbs, nor Indian peaches. The best are the cheapest.

REFORMATION, OR BANKRUPTCY AMONGST PLANTERS IN THE COTTON STATES.

It does not require the prescience of a prophet to deter nine that cotton planters must make considerable retrenchments of expenditures, or submit to ruinous sacrifices of property. At the present prices of cotton, even his six bales of cotton to the hand, with his supplies of stock and provisions, will not more than save his capital, without affording any surplus, or very little, for the support of his family. The hopes of a better market have so long deluded the cotton planter, that further disappointments cannot be borne; while a revolution in the market, for the better, is very uncertain, at least for a few years yet. The most rigorous economy must be submitted to, or bankruptcy. "A prudent man foreseeth the evil, and hideth himself; but the simple pass on and are punished."—When too late, many will learn that it had been wiser to live a few years upon bread and water, and wear sackcloth, than to cast their children, unaccustomed to labor and hardships, upon the world, to live by the sweat of their brow, or perish. Two or three years of rigid economy in dress and equipage, with a double energy in the increasing and saving productions of our plantations, (if not too late,) may secure independence, when one year more of usual extravagance would prove ruinous. Most planters have, no doubt, taken the alarm, and have made double effort to increase productions, raise all their stocks and provisions, and have ceased speculations. This might have saved a wreck, with a cotton market averaging 8 cents; but this will not now do, the reformation must go further. Not 50 per cent must be cut off from the expenses of high living, dress and equippage. To human nature, this will be like plucking out the right eye. It is pleasing to human nature to climb to high stations of life, but revolting to dome down; yet it is better to walk down than to fall. Parents personally may submit to the self-denial; but giddy sons and daughters will not see or feel the necessity. For parents to have the moral courage to enforce a law of rigorous retrenchment, against the murmurings, entreaties, or haughty insinuations of children, will require almost the holy fortitude of Abraham in offering up his son Isaac. It will not be hard for you, parents, to return to your old-fashioned homespuns again, as in old times. But what think you of reducing your sons' cloth from $8 or $10 to $4 or $5 per yard, and other expenditures in proportion? What think you of substituting for the piano the needle and thimble? Of encouraging the honest industry of daughters, instead of the extortion of tailors and mantua-makers? Of substituting a plough and mule for your son's hounds and hunter? Think as you may, reformation must be extended in all of these classes of expenditures, more or less, or suffer worse consequences, if cotton planting is your only source of income. If planters in general would commence with simultaneous action in the work, the mountain would be soon levelled to a plain. Custom would remove the mortification of seeming inferiority. Let those whose circumstances would enable them to bear the pressure, as patriots, set the example, and the victory is gained.—Further, such a rigid course of making and saving would inspire confidence in creditors, and thereby indulgence would be secured. The unfeeling creditor who would grind and oppress the honest debtor who was making every edge cut, and even cutting off many of the common comforts of life from his family, in order to pay his debts, would bring down the indignation of the public mind upon himself, and excite the sympathies and secure friends in behalf of the honest debtor. We have already witnessed a benevolent and noble disposition with creditors, (with a few exceptions,) to indulge where there is confidence of security, and especially among our bank officers. And if the frugal, saving and honest planter, after all his hard struggles and sacrifices of comfort under a depressed market and distracted currency, beyond the calculations of the most experienced commercial men and wisest financiers, should fall by the hands of his oppressor or some unfeeling speculator, there will be a refuge for the oppressed, who has fallen under honest struggles instead of extravagant living, which will enable him to go down to his grave in peace. And if he leaves his family to inherit honorable poverty, it will prove a better legacy than dishonorable wealth.

If the planters, however, will, in time, with determined purpose, carry into full effect the doctrine of retrenchment; look well to their own plantations, rather than trust too much to overseers; raise all that can be raised for the use and consumption of their plantations; put their sons to the plough and daughters to the needle; feed negroes and brutes well, and make all move in their stations; bring overseers to the mark, and make them bestir themselves, or dismiss without ceremony. Let them also take an agricultural paper, and believe nothing they read there without good evidence; nor reject any discovery with evidence; and one article may afford them sufficient information to pay 500 per cent on the cost of the paper. Let them look well to their legislators, vote for men of sound wisdom, of pure moral and patriotic principles, who can and will speak and act when necessity calls for it. Let them take care of weathercocks and popinjays. Let creditors be patient and merciful. Let debtors be honest and candid, paying as fast as possible, and avoid all low devices towards their indulgent creditors; and, above all, pray for blessings upon their honest labors, to Him who alone can give the increase, and can make *hard times* prove blessings in disguise. But take warning, planters, and be at least as wise as the burnt child; risk no more speculations or big debts, (even if cotton should ever rise again to 20 cents per pound,) and if you do, calculate to pay debts at the rate of six cents, and you will be sure to make a saving calculation, and not risk the ruin of your estate again. If cotton rises, still raise your stock and provisions; stock makes manure; too much cotton allows no time to make manure; a few acres well manured makes more than treble worn out. Seed your waste lands with valuable grasses, which raises stock with the least expense, saves or improves lands, and will not be in the way of cultivating or picking out the cotton crop. The Kentucky hemp-grass is thoroughly proven to suit our soils and climate, and one sowing is for life, easily killed when needed, and affords grazing all winter. The herds grass is also proven and will grow best on marshes and branch bottoms fit for little else, and grows in winter, and in March covers the ground with verdue. We have native summer-grasses plentifully, and if we secure winter pastures, little expense of grain will be required to excel Kentucky in stock, as our climate favors the winter growth of grasses better, and our winters are milder, and therefore favorable to raising stock. If the depressed state of our cotton market should drive planters to economy in living, to improving lands, raising stock, diminishing the production of cotton in our own cotton States, and driving the Indian cotton planter out of market, all will work together for final good, (if not wrecked in the storm,) and one year more, perhaps, of arduous and prayerful perseverance, the danger may be over, and Carolina planters in the harbor of safety.

MONTICELLO.
Planter.

☞He is a public benefactor who, by the prudent and skilful outlay of his time and money, shall make a single field yield permanently a double crop; and he who does this over a square mile, virtually adds a square mile to the national territory—nay, he does more: he doubles to this extent the territorial resources of the country, without giving the state any larger territory to defend. All hail, then, to the improvers of the soil! Health and long life be their fortune—may their dreams be few and pleasant, and their sleep the sweet repose of the weary—may they see the fruits of their own labor, and may their sons reap still heavier harvests.—*Black. Magazine.*

TO FARMER'S DAUGHTERS.

I have talked to you so much about every day business, you will think it the only matter I consider any way important; I can assure you this is a mistake. I look upon mental culture as of equal moment, but as all the wise heads in creation discuss this topic, I leave it with them, and again take up the old theme of work, work.—"spring time of year is coming," or to use the language of the old poet Solomon, "the winter is past, the rain is over and gone, the flowers appear on the earth, the time of singing of the birds has come, and the voice of the turtle is heard in our land." Nature will soon enrobe herself in her rich green mantle, tastefully interwoven with flowers of every hue, from the colourless lilly, to the deep dye of the rose and peony. Now, you can assist the noble Dame in the arrangement of her toilette. She is like some other ladies, and loves to be decked with bright ornaments.

You can embroider the hem of her garment, put here a leaf and there a flower; in another place a small tree, shrub or vine, and you may finish off with an edging of Purple Shade, or rows of White Fringe or Purple, as may suit your taste. Should any parts of her mantle be neglected, fill up with a rich border of strawberries, and dot with the golden pear, snow peach or blue plumb.

But to go on in a plain old fashioned way, now is the time for gardening, and as it is a most delightful employment, I want to speak to you of your taking an interest in it. There is none more calculated to improve the minds, as well as the physical powers of the young. It has a more soothing and happy influence than almost any other. Go into the garden when you are listless and low spirited, (as you often find yourselves when you do nothing useful) plant some shrubs or flowers, set out a bed of strawberries, use the rake or hoe industriously in finishing off borders, form a plantation of raspberries or any thing else necessary or pleasant, and by the time you feel like resting, all your hyppo will be gone, and you will wonder why you have not found out before, that the garden is the place to frequent, if you wish to be vigorous and in good spirits. The rage for flowers of all kinds is becoming so fashionable now, that any one who is not fond of them is almost wondered at. In this part of the country you see ladies handling the spade and other tools.

Spading, hoeing and raking are quite *a la mode* in our region. I was riding through town some time since, and passing a garden where every thing was in a flourishing order, I noticed a lady with her spade, and her manner of using it could not have been excelled by Gen Jackson himself. The gentleman who was with me, has not done praising her yet. You may say, I have no taste for flowers. The right way to obtain this is to go to work. I knew a young lady who had no fondness at all for flowers, and never thought of cultivating any. She received a present of a rose or some other little shrub in a box. At first she cared but little for it, but after a time, when the buds began to expand, she was attracted by its sweetness and beauty, and by degrees her love for it increased, until she wondered she could care so much for a flower. She began to collect slips of different plants, to tend them with the most watchful care, and she soon had a very pretty collection. Now every little bud that blows, every fresh leaf that puts forth, seems to give her so much pleasure, and she would not be deprived of the enjoyment their cultivation affords, for any consideration.

If your homes are destitute of flowers and shrubs, you could, in a short time, so much alter their appearance by planting them out. You can do it yourselves, and you will take more interest in them than if your parents were to do it. In travelling I have passed so many houses where not the least flower might be seen, and the thought always came over me, there is not much care taken at that place to render life pleasant—to throw around the inmates any of its sweetnesses; to lead them to refinement and

love of home; and again, when I have passed a cottage surrounded by trees, shrubs, vines and flowers, I have thought there is the abode of a woman of delicacy and taste. It is really cheering to the eye of the weary traveller to meet with these things, and he would rather stop to rest, where pains had been taken to tend them, than where it was desolate and bare.

I speak of these things, because it is peculiarly the province of woman to study whatever makes life agreeable and divests it of what is unpleasant. The more sources a woman has of enjoyment, the better it is for her. It is her lot, if she is domestic and discharges her duties as she ought, to stay at home; it is her lot to be often alone, and also to participate largely in the cares and anxieties of life. Active exertion is often a relief to many of these, and in no part of her establishment can she make it with so much pleasure, as in her garden. Girls should learn more of these things, so that when settled, they may seek for enjoyment at home, by performing their duties, and not make it their chief enjoyment to visit and pass about from place to place. I would say again to you, to go to work, cultivate the useful and beautiful, and you will not regret the time you have thus spent. You will not look back and say, it was unprofitably employed. LUCY.

Tennessee Agriculturist.

TREATMENT OF COWS—BUTTER MAKING.

Change of Pastures.—To insure the production of the largest quantity of butter, a frequent change of pasture is required. A farm should be so fenced that the cows can be changed into a very different lot every four or five days.

Salting.—A constant and full supply of salt should lie before our cows in some secure place. They will eat moderately what they require.—If only occasionally furnished, they often take it in quantities so large, as to act medicinally to their injury. It corrects almost any bad quality of the milk, arising from the eating of aromatic or bitter herbs, and also much of the natural animal odor, that frequently impairs the sweetness of butter.

Driving—kind treatment.—Many a faithful cow has been seriously injured by a careless boy driving her furiously to and from the pasture. All harsh treatment of any kind, as scolding, striking, kicking, &c. is all detrimental. I have known many cows rendered worthless from these causes. The utmost kindness and gentleness of manner must be shown on the part of those who manage our stock.

Milking.—This process should be done systematically, at regular periods of the day. Sunrise and sunset are perhaps the best periods; for immediately after the one, and before the other, cows in hot weather feed to the best advantage. They are so much creatures of habit that the milker should be changed as rarely as possible. A stranger is always regarded as an unwelcome visiter, by a milch cow.

Cleanliness with the utensils.—The pans, pails, strainers, bowls, churn, and every implement employed in butter making, must not only be well washed, but they must be thoroughly scalded with boiling hot water, and be perfectly dried afterwards, either in the sun or before the fire. This must be repeated every time they are used. Merely pouring boiling water upon them when loaded with sour milk or cream, will only serve to scald in the bad flavor, if I may use the expression. Wash them at first, and then scald them thoroughly, if you would have sweet butter.

There are certain filthy practices which slatterns fall into, that should be corrected; such as wetting the cow's teats with milk, and permitting it to drop into the pail; milking in the morning without washing their hands, &c.

Milk-house and Buttery.—In hot weather a good spring-house is necessary for the making of butter. It must be constructed of either brick or stone, and in no instance of wood, as that article never fails, in such a situation, to become mouldy, and impair the flavor of butter. It must be built so that it can be thoroughly ventilated. A window should be placed on the north, east and west sides, which must be furnished on the outside with wire gauze screens, and on the inside with tight shutters. During the day, the shutters must be closed, and at night must be raised.

A spring may be dispensed with—and it is even problematical whether it does not, upon the whole, do as much injury by imparting dampness, as it does good by lowering the temperature. A well constructed house without the spring, will answer the purpose. It should be shaded with trees or arbors of grape vines. All mouldy and decaying wood-work, boards, boxes, &c. must be kept out of it; also all foreign substances, as meats, fish and vegetables. The air of my spring-house was ruined for a week or more, merely by placing in it a few mackerel.

Skimming the Milk.—In hot weather the milk may be allowed to curdle before this operation is performed, but if it be delayed any longer, a thin, watery fluid will form between the milk and the cream, after which the good qualities are inevitably destroyed. It is necessary, in midsummer, to skim the milk every morning and night. This point must receive the strictest attention. Neglect of it often gives a streaked or mottled appearance to butter, as well as impairs its flavor.

Cream.—As soon as it is collected, it should be placed in a stone crock, which should either be hung into a well, or set up to the brim in the spring within the milk-house.

Churning.—This operation must be resorted to as soon as a supply of cream is obtained, and in hot weather cannot safely be delayed beyond the third day.

A variety of patent churns have been palmed upon the public, none of which, we believe, is to be preferred to the old fashioned upright dasher, or the barrel.

Working of Butter.—This must be repeated until every drop of the buttermilk is expelled; twice or three times will be necessary, nor must it be delayed too long, till a change begins to take place in the remaining buttermilk, as that will impair the flavor of the butter, which no subsequent treatment can restore.

Salting.—The salt should be added at the commencement of the first working. Much of our western butter is injured by the employment of the common New York salt. The finest *ground* articles should be used. It can now be obtained in sacks, of our merchants, at reasonable price.—*Cleavetand Herald.*

MILKING.

Cows that are milked quick and stripped clean will give more milk than if they are managed by moderate milkers. The reason is, that whatever milk is left in the udder dries up, and a cow will shrink in her milk permanently in proportion to the quantity that is allowed to dry up. If half dries up, she will soon be reduced to half her natural flow of milk; just as she will dry totally up if her milking is totally neglected.

When a milker approaches the cow, the animal is said to "give down" her milk. From that moment it should be withdrawn as rapidly as possible; the longer it or any of it remains in the udder, the more of it begins to dry up, even during the operation of the milker. Very much depends upon rapidity and fidelity in the milker, in order to boast truly of having an excellent cow for milk. We have known cows that in certain hands gave enormous quantities of milk, and as soon as they were sold to a villager, who trusted to his hired girls to do the milking, they begun to shrink, and soon the cows lost their reputation, and the men of whom they purchased were denounced as liars, cheats and every thing else that is bad. The secret of this faultfinding might be traced to the girl, who either was very slow in milking, or who had not patience enough to strip the cow very clean.

If a cow was not managed aright when she had her first calf, it will be almost impossible to make her great for milk as long as she lives. The first experiment with her is a final habit.—No heifer, after calving, should be trusted to inexperienced, unkind or unfaithful hands. She should be treated gently, fed well, and milked regularly—at just such hours—and milked quickly and as long as half a dozen drops can be forced from the udder. She should, too, be milked as nearly as possible up to the time of her having the next calf. By such attention, she will be likely to prove a valuable animal; one that will give much milk, hold out long, and be manageable every way by her attendants.

Learners should be taught the art of milking on cows that are being dried off. And one of their first lessons should be to clasp the teat very near its extremity. This will hurt the cow least, and be worked easiest to the milker. They should also bear the left arm moderately against the leg of the cow. She cannot then kick, or if she attempts it, by raising her foot, the milker will be ready to ward off and protect herself and pail from any sad consequences. Thus guarded, let them make as brisk work of milking as possible—treating the cow gently, and withdrawing all the milk faithfully, and there will be a chance for the security of two good things—a good milker and a good cow.—*Gos. Banner.*

NIGHT SOIL.

To the editors of Tennessee State Agriculturist:

There is much said in your and other agricultural journals, about the advantages of night soils, as a manure. One of your subscribers in this part of the country, wishes to be informed about the matter as follows:

1. What is it mixed with, and in what proportion to destroy all disagreeable odor?

2. What is it mixed with, and in what proportion, to prepare it for the soil?

3. How is it used as a manure, for top-dressing, sowed broadcast, or put in the ground and covered. Please give the whole modus operandi, and all else that you may deem necessary on the subject. Give the desired information thro' your paper. Very respectfully.

R. HOUSTON.

REPLY.

The above enquiries we consider of vast importance to all who till the earth far a support. Agricultural chemists and the most intelligent farmers and gardners, agree in commending night soil, or human excrements, above all manures. Its superiority arises from the fact that it contains a greater quantity of ammonia than other manures. The preparation is a simple process, and attended with very little expense or labor. Mr. Woolfin, in the Southern Planter, gives his mode of making and applying Poudrette, which not only accords in the main with other writers, but the process is presented in such a manner it cannot be misunderstood.—He says:

"I collect the stercoraceous matters separately in large vessels or hogsheads, after the urine has become putrid, which will require but two or three days in warm, and ten or fifteen in cold weather. I then add sulphuric acid to the urine slowly; if the urine is putrid, a powerful effervescence will immediately take place; the acid must be added until effervescence ceases. By this process, the carbonic acid in combination with the ammonia, is disengaged and driven off, and sulphate of ammonia is formed, which has no volatility, except at a very high temperature. Thus you secure the ammonia formed by putrefaction, which otherwise would escape. I then add the liquid to the solid excrements, incorporating them well together, until a very thin batter is formed; into this mass I stir in finely pulverized charcoal, according to my judgment, without regard to any precise quantity; this done, I spread the mass upon boards made tight, in the open air—stir frequently until the whole is dry, then pulverize with a spade and barrel it up for the use of crops.

My drying boards are protected from the weather by a shed open to the south, so as to receive the benefit of the sun. Manure made in this way I call Poudrette, and of its value I

can speak in the highest terms. When properly made, it is inodorous, and the application to crops easy, and the effect powerful. I made an experiment with it last season upon sugar beet, in comparison with bone dust, bone dust and stable manure mixed, and stable dung alone. The beets manured with poudrette, came up quicker, grew faster, and maintained a decided superiority to the last, making the largest and best beets; the quantity of poudrette was only a small train to each drill. I used it also upon corn with entire success. In this experiment I subjected it to a very severe test; I selected a very poor spot, put only one and a half gills to the hill as a top dressing, at the time of planting, and the result was truly astonishing, proving it to be beyond all doubt a manure of great strength and power, perhaps surpassing all others now known.

It must in all cases be used as a top dressing; such is its strength when planted with seed, the germ is destroyed, and consequently does not come up."

In addition to the above, farmers and others who wish to prepare night soil, must be careful not to mix lime, or soil with a large proportion of lime, with it. If sods and earth of almost any kind were placed so as to absorb the excrementitious matters, and applied to crops in this manner, no doubt they would be much increased. Liebig said, a pint of urine would produce a pound of wheat; we may safely calculate other crops would be as much benefitted. We wish to hear if any of our readers have experimented with night soil, and with what success.

Comparative nourishment of different Vegetables.—If, as an article in the last Cabinet, signed "Vir," states, "the differences of opinion with regard to the value of root crops, as cattle feed, are indeed about as different as light is from darkness," the following table, showing the comparative nourishment of some of the principal kinds of vegetable food, may possess interest. The table was formed by Boussingault, an eminent French chemist—and he tells us that he compared the result of his experiments with the practical experience of farmers in feeding cattle, and found "a most remarkable coincidence between the theoretical and practical inference." The table is from a late number of the Boston Medical and Surgical Journal, and is as follows:

White French beans	100
Yellow peas	120
Farina of cabbage	148
" of carrots	170
" of wheat	175
Wheat	191
French wheat	193
Rye	200
Farina of barley	212
" of potatoes	225
Barley	232
Indian corn	246
Potatoes	1096
Carrots	1361
White cabbage	1446
Turneps	2383

"Thus we see that 100 parts of white French beans are equivalent in nutritive power to 110 parts of yellow peas—to 1096 of potatoes, and 2363 of turneps. A farmer, for example, in feeding cattle, would find that 420 parts of yellow peas, would go as far in keeping up the strength and efficacy of his cattle as 2383 parts of turneps. Or it would require more than 23 bushels of turneps, or 2 bushels of rye, to be equal in nutritive power to one bushel of white French beans.

These statements, it is believed, may be relied upon as approximating the truth; though the fact, that it should require nearly two bushels of wheat to equal in nutrition one of beans, may be a little too many. When farina is given, as of cabbage, potatoes, &c. the meaning is, that the article was dried and reduced to flour, by grinding or otherwise.—*Farmer's Cabinet.*

COMPARATIVE VALUE OF DIFFERENT KINDS OF FODDER FOR CATTLE.

A table of the comparative value of different kinds of fodder for cattle has been published by M. Antoine, in France, and is the result of experiments made by the principal agriculturists of the continent, Thaer, Gemerhausen, Petro, Rieder, Weber, Krantz, Andre, Block, De Dombasle, Boussingault, Meyer, Plotow, Pohl, Smee, Crud, Schwertz, Pabst. It is unnecessary to give the figures which each of these experimentalists have set down, but the mean of their experiments being taken, there is more chance of the result being near the truth. Allowance must be made for the different qualities of the same food on different soils and different seasons. In very dry summers the same weight of any green food will be much more nourishing than in a dripping season. So likewise, any fodder raised on a rich dry soil, will be more nourishing than on a poor wet one. The standard of comparison is the best upland meadow hay, cut as the flower expands, and properly made and stacked, without much heating; in short, hay of the best quality. With respect to hay, such is the difference in value, that if 100 lbs. of the best is used, it will require 120 lbs. of a second quality to keep the same stock as well, 140 lbs. of the third, and so on, till very coarse and hard hay, not well made, will only be of half the value, and not so fit for cows or store cattle, even when given in double the quantity. While good hay alone will fatten cattle, inferior hay will not do so without other food.

100	lbs.	of good hay is equal in nourishment to
90	"	" hay-made clover, when the blossom is completely developed.
88	"	" ditto, before the blossom expands.
98	"	" Clover, 2d crop, is equal in nourishment to
98	"	" Lucerne hay,
89	"	" Sainfoin hay,
91	"	" Tare hay,
146	"	" Clover hay, after the seed,
410	"	" Green clover,
457	"	" Vetches or tares, green,
275	"	" Green Indian corn,
541	"	" Cow-cabbage leaves,
374	"	" Shelter wheat straw,
442	"	" Rye straw,
164	"	" Oat Straw,
153	"	" Peas halm,
159	"	" Vetch halm,
201	"	" Raw potatoes,
175	"	" boiled "
339	"	" Mangold wurzel,
504	"	" Turneps,
276	"	" Carrots,
308	"	" Swedish turneps,
305	"	" do do with the leaves on,
54	"	" Rye,
45	"	" Wheat,
54	"	" Barley,
59	"	" Oats,
50	"	" Vetches,
45	"	" Peas,
45	"	" Beans,
64	"	" Buckwheat,
57	"	" Indian corn,
68	"	" Acorns,
50	"	" Horse chesnuts,
62	"	" Sun flower seed,
69	"	" Linseed cake,
105	"	" Wheat bran
109	"	" Rye bran,
167	"	" Wheat, pea and oat chaff,
179	"	" Rye and barley chaff.

Lattermath hay is good for cows, not for horses. The second cut is generally considered as inferior in nourishment to the first. New hay is not wholesome. At Paris, when a load of 1000 kilos is bargained for, the seller must deliver—if between hay making and October 1, 1300 kilos—and after April, only 1000. This is fair, and allows for loss of weight in drying. In London, a load of new hay is 20 cwt., of old hay, only 18 cwt.

The dried half of the Trifolium incarnatum, after the seed is ripe, is little better than straw. Clover, lucerne and sainfoin, are generally supposed to lose three-fourths of their weight in drying; but in general they lose more, especially in moist climates, where the sap is more diluted. When touched by the frost, they become very unwholesome, and should never be given to cattle except quite dry.

Straw is, on the whole, but poor food, and unless cattle have something better with it, they will not keep in any condition; when given with turneps or other roots, straw corrects their watery nature, and is very useful; cut into chaff it is very good for sheep when fed on turneps, and when newly thrashed is as good as hay. By a judicious mixture of different kinds of food, a more economical mode of feeding may be substituted for a more expensive one, and the same result obtained. The value of straw depends much on the soil: a very clean crop will not give so nourishing straw as one containing many succulent weeds. Peas and vetch halm are superior to straw, especially when cut into chaff: it is by some thought equal to hay. The same may be said of bean halm not left too long in the field, and cut before it is completely dry. Buckwheat halm is of little value: it is thought unwholesome if given to sheep.

16 lbs. of raw, or 14 lbs. of boiled potatoes will allow a diminution of 8 lbs. of hay.

Turneps will feed store pigs, but they will not fatten on them. Carrots and parsnips are excellent for horses, and, when boiled, will fatten hogs. Ruta baga is liked by horses; it makes their coats fine, but must not be given in too great quantity, or it will gripe them.

Feeding.—A certain quantity of food is required to keep an animal alive and in health: this is called his necessary ration of food: if he has more, he will gain flesh, or give milk or wool.

An ox requires 2 per cent of his live weight in hay per day; if he works, he requires 2½ per cent; a milch cow 3 per cent; a fatting ox 5 per cent at first; 4½ per cent when half fat; and only 4 per cent when fat; or 4½ on the average. Sheep grown up take 3½ per cent of their weight in hay per day, to keep in store condition. Growing animals require more food, and should never be stinted.—*Jour. Royal Agr. Society.*

EXERCISE.

Many people look upon the necessity man is under of earning his bread by labor as a curse. But it is evident from the structure of the body, that exercise is not less necessary than food for the preservation of health; those who labor are not only the most healthy, but generally the most happy part of mankind. This is peculiarly the case with those who live by the culture of the ground. The great increase of inhabitants in infant agriculture every where, evidently proves it to be the most healthy, as well as the most useful employment.

Next to total abstinence from all intoxicating drinks, nothing contributes more to the preservation of health than early rising and exercise in the open air in the morning, when the air braces and strengthens the nerves. Custom soon renders early rising agreeable.

Every person should lay themselves under some sort of necessity to take exercise. Indolence, like other vices, when indulged, gains ground, and at length becomes agreeable.—Hence many who were fond of exercise in the early part of life, become quite averse to it afterwards. This is often the case with gouty or hypocondriac persons, and frequently when their diseases are difficult to cure.

Indolence not only occasions diseases, and useless to society, but promotes all manner of vice. The mind if not engaged in some useful pursuit, is constantly in quest of some ideal pleasures. From these sources proceed most of the miseries of mankind. Certainly man was never intended to be idle. Inactivity frustrates the very design of his creation, whereas an active life is the best and greatest preservation of health.—*Oracle of Health.*

WEDNESDAY, MAY 3, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

SPLENDID BERKSHIRES.

Within the last few days we have enjoyed the pleasure of looking upon the finest specimens of the Berkshire hog that we have ever seen, and we doubt not the finest ever introduced into the Southern States. They are a recent importation, eight in number, of our enterprising fellow citizen, Col. JOHN BONNER, of Green county, who has so deservedly distinguished himself as a breeder and raiser of fine hogs at the South. Two of them, *Ontario* and *Lady Huttleston*, decidedly the best specimens of the hog we ever saw, were imported from England by the Messrs. Brentnall, of New York, and were bred by that celebrated English stock raiser, SIDAY HAWES. The other six, one of which is a male, were bred in America, and for high form and fine symmetry are truly models. Col. BONNER deserves much at the hands of his brother planters in Georgia, for the zeal and enterprise he has manifested in the improvement of our stock of hogs, and we sincerely hope, and we doubt not, he will reap a reward commensurate with his merits. Those who desire to avail themselves of an opportunity to improve their stock, can obtain pigs from Col. B. at twenty dollars a pair. Address JOHN BONNER, White Plains, Green county, Georgia.

COTTON SEED FOR COWS.

The *Planter* notices our remarks on the subject of boiled cotton seed as a food for milch cows, and makes the following comments, which appear very judicious:

COTTON SEED FOR COWS.—The last Southern Cultivator recommends boiled cotton seed as an excellent article of food for milch cows. They certainly produce thicker cream, and a greater amount of butter; but we would respectfully suggest to our neighbor, that they will not do alone. They impart an unpleasant flavor to the milk, and give the butter a tallowy texture and taste. If, however, one third (or even one half) cotton seed, with two thirds of corn meal, or peas, are fed to milch cows, they produce very rich milk and butter, and impart no unpleasant flavor. In addition to the unpleasant flavor of the milk, when cotton seed alone are used, we think they tend to impair the health of cows. It is well known that cotton seed contain a very large quantity of oil, (and it is this constituent that makes the cream so rich,) which though wholesome and nutritious in moderate quantities, renders the cotton seed an unsafe food to be used alone, in large quantities, and for a length of time. If used alone, the food should be changed frequently. In the proportions we have mentioned, however, no better winter food for cows can be obtained.

We think every planter would do well to preserve a hundred or two bushels from the weather every fall; but never feed them in the raw state.

CURING SWEET POTATOES.

The subjoined correspondence has been sent us, to which we give place with pleasure, with the hope that it will lead to some valuable suggestions through our columns. We would, therefore, thank those of our planters who have been successful in saving their potatoes, during the winter, to give us their plan, in detail, that we may lay it before the readers of the Southern Cultivator.

—

EATONTON, GA., April 8, 1843.

DEAR SIR—Having accidentally seen an article in the Southern Miscellany, of yours, in regard to raising Sweet Potatoes, and which appears to be much approved of by my neighbors, I would be greatly obliged to you, and take it as a particular favor, (if convenient,) to give me your mode of putting them in the ground; to preserve them from rotting; the mode of hilling them; what is best to be used for the purpose? whether of straw, shucks, corn stalks, &c. &c.

I was so taken up with the article, that I determined to give you a few lines on the subject, for information to myself and neighbors; for they all admire your plan, and intend to follow it, they say, to the very letter; and you may be sure that I shall do so, as I am now just laying off my ground for the very purpose. Please answer this as soon as convenient after its receipt, and pardon me for the liberty which I take with you, for troubling you with this communication. Any other information on the subject will be gratefully received.

Very respectfully, &c.

J. S. PENNIMAN.

Mr. W. MCKINLEY.

—

LEXINGTON, April 14, 1843.

Mr. PENNIMAN—Yours of 8th instant was duly received. I am sorry to say that I have not been over-lucky in *keeping* potatoes; not half so much so as in *making* them. Last fall I was very unlucky, as I was caught by the hard freeze about the 20th of November. The year before I kept them very well, without any potato-house or scaffold, in the open air, covered moderately with broomstraw and earth. They kept soundly all winter. In November, I was careful to let the piles remain naked, (except in frosty nights,) for about ten days, so as to air or dry. You have doubtless noticed that a big potato will shrink much, in a few days, if left lying about a house. This shrinking is caused by evaporation of its juices, and in case of a large bank is very useful, as it lessens heat and sweating. I have no doubt of the constant propriety of this airing or drying of the heaps, when the potatoes are to be kept, as is usual, above ground, and I have observed that some of the inhabitants of the lower country continue this exposure a long time. I remember that one man, a good potato-grower, in Decatur county, once showed me his banks in this naked state so late as Christmas, with nothing over them but a little pine straw—no earth at all.

But if I mistake not, a better way than all, is to keep the potatoes *under ground*, with earth largely mixed among them. This is the *natural* way. Irish potatoes keep so finely. And it seems to me, all we have to do, is just to cover them deep enough to keep them *below the freeze*. Last April I saw potatoes ploughed up as sound and good as in October; and I intend to try this mode next winter. But this, at present, is theory.

A correct answer to your enquiry is very important to the up country, as immense loss is yearly suffered by the mass of people not knowing how to preserve this great article of food; and to secure fuller information, I will send your letter to the editors of the Southern Cultivator, who will, no doubt, call for information on the subject from their readers.

I am glad to learn that you and some of your neighbors will plant in the way described in my letter to the Southern Cultivator, which you saw in the Southern Miscellany. I doubt not you will double your crop. Yours, &c.

W. MCKINLEY.

SOAP MAKING.

Much difficulty is often experienced by those who manufacture their own soap; frequently indeed the operation succeeds well, but sometimes it totally fails from unknown causes. Often when every precaution has been apparently taken, complete failure has been the consequence; and the time is not long past, when some have even declared that they believed their soap was *bewitched*. But if the rationale on which the process is founded, is but understood, the whole becomes simple and easy, and may be performed with absolute certainty of success.

Common soft soap is composed of oil (or fat) and potash. The potash is obtained from common wood ashes, by causing water to run thro' it, which dissolves the potash contained in the ashes, and leaves the residue behind. The manner by which the oil or grease is obtained is well known. These are made to unite and form soap by being boiled and well stirred together.

One of the first requisites in soap making is that there should be a sufficient quantity of potash dissolved in the water, or in other words, that the ley should be *strong:* this is readily ascertained by an egg; if the egg floats the ley is sufficiently strong; if it sinks, it is too weak, and must be increased in strength by evaporating a part of the water by boiling, or by passing it again through ashes.

But it not unfrequently happens that the ley is found by trial to be too strong, and yet good soap cannot be produced. This is almost always owing to the potash of the ley not being *caustic*, or capable of corroding the skin, which state is absolutely requisite to success. Potash in its purest state is highly caustic; but when ashes have been for some time exposed to the air, they gradually absorb from it a portion of the peculiar kind of air, existing in small proportion in it, known by the name of *carbonic acid*, which destroys the caustic properties of the potash and renders it unfit for the manufacture of soap.—Now, as quick lime has a stronger attraction for carbonic acid than potash has, it is only necessary to place a quantity of lime, in the proportion of half a bushel of lime for a hogshead of good ashes, in the bottom of the leech before filling it, and it will abstract the carbonic acid from the potash of the ley, as it passes downward, leaving it in a comparatively pure and caustic state. In order to prevent failure, therefore, this should always be done. In order to ascertain if ley contains carbonic acid, pour a few drops of sulphuric or nitric acid into a wine glass of the ley, when, if it contains much, a violent effervescence (or boiling up of bubbles)

will instantly take place, owing to the escape of the carbonic acid. The carbonic acid may be removed from they ley and rendering it fit for soap making, by boiling the ley with quick lime

If the ley be strong, if it be rendered caustic, and if there be a sufficient quantity of tolerably clean fat, there can be little danger of success. The proportions should be about thirty pounds of fat to eight or ten gallons of ley.

Hard soap consists of soda instead of potash, united with fat; and is commonly made by adding common salt, (which consists of muriatic acid and soda,) to well made soft soap while it is yet boiling. The soda of the salt unites with the fat, and forms hard soap, while the potash unites with the muriatic acid of the salt, and separates by falling to the bottom of the vessel.—Different degrees of hardness in soap are obtained by using potash and soda, at the same time in different proportions. Hence grease from salt meat has a tendency to increase the hardness of soap, unless the salt be removed by boiling in water.

Soap of tallow is made in England, and largely in the United States, and is the best in common use. When scented with oil of caraway seeds and cast into a mould, it is used for the toilet, and is called Windsor soap. Other toilet soaps are made with butter, hog's lard, or with almon, nut or palm oil. Sometimes fish oil is used for coarse soaps, as well as linseed oil; and rosin is often added to give a yellow color and odor. The following proportions, by weight, have been given for a good yellow soap; tallow twenty five, oil four and a half, rosin seven, barilla (soda) eighteen, settlings of waste ley, evaporated and calcined, ten, and palm oil one half part.

Soaps are colored blue by indigo, yellow by tumeric, &c.; and marble or veined soaps are made thus: to the soap just separated from the spent ley, new ley is added, and then copperas dissolved in water, red oxide of iron (or colcother) mixed with water is stirred in it by manual dexterity, and is so mixed as to produce the peculiar appearance.—*Genesee Farmer.*

PREMIUM CROPS IN NEW YORK.

INDIAN CORN—*First Premium*—112 *bushels per acre.*

On the 22d day of May, 1842, I ploughed up one acre of green sward, for the purpose of planting it with corn. After ploughing it once, I harrowed it well, lengthwise of the furrows. I then marked out the ground so that the rows and hills should stand precisely two feet apart either way. On the 25th of the same month I planted it, and was careful to put precisely three kernels in each hill; when it was large enough, I hoed it, and continued to hoe it three different times. No other tool was used in the process of hoeing and cutting up the weeds, but the hoe; being very careful to keep the weeds and grass down as much as possible, and in hoeing, to leave the ground as near level as possible each time.

I permitted the corn to stand until it was fit for harvesting, without cutting or topping.

Between the 10th and 15th of November, I began to husk it, and also to weigh the said corn. I found the aggregate weight from the said acre, in the ear, 13,286 lbs. of a good quality.

About the first day of January, 1843, I thrashed out all the sound corn that grew on said acre and measured it in a sealed half bushel, and weighed it, and found that it fully held out 60 pounds to the bushel, and it produced me one hundred and twenty two bushels of good merchantable corn. My team and man were occupied one day in ploughing the said acre, half a day harrowing, 2 days labor planting, and six days hoeing, and six days harvesting, threshing and weighing.

122 bushels corn, at 37½ cents	$45 75
Expenses	14 00
	$31 75

SAMUEL PHELPS.

Ira, Cayuga co., January, 1843.

HOW TO COOK POTATOES.

There is reason in roasting eggs, says the old adage, and there is not one in a hundred who knows how to roast them properly. Still fewer know how to boil potatoes, simple as the process is deemed. We love a good, well cooked, mealy potato, and all our readers, sensible men as they are, no doubt like the same tuber, but how often do we see the very best potatoes brought on the table, heavy, drenched, saturated with water, and utterly unfit for eating. To prevent such atrocities in future, we copy the following from a poem of some length in the Southern Literary Messenger, devoted to teaching the art of planting and cooking potatoes.

Army & Navy Chronicle.

Wash them clean and scrape the skin off,
One water never is enough,
Take the eyes and nubbins then off,
And every little speck that's rough.

Do not let them lie in water,
(So the nice observers say,)
Not a minute, not a quarter,
That will take the taste away.

When the fire is burning brightly,
And the water's boiling hot,
Sprinkle table salt in lightly,
Then put the kidney in the pot.

Eighteen minutes, sometimes twenty,
Cooks them nicely to a turn,
Some say more, but that is plenty,
Every one must live and learn, &c.

"The following beautiful description of the person of Jesus Christ was found in an ancient manuscript, sent by Publius Lentulus, President of Judea, to the Senate of Rome:

"There lives at this time in Judea, a man of singular character, whose name is Jesus Christ. The barbarians esteem him a prophet, but his followers adore him as the immediate offspring of the immortal God. He is endowed with such unparalleled virtue as to call back the dead from their graves, and to heal every kind of disease with a word or touch. His person is tall and elegantly shaped, his aspect amiable, reverend. His hair flows in those beautiful shades, which no united colors can match, falling into graceful curls below his ears, agreeably couching on his shoulders, and parting on the crown of his head, like the head dress of the sect of the Nazarenes. His forehead is smooth and large, his cheeks without spot, save that of a lively red; his nose and mouth are formed with exquisite symmetry; his beard is thick, and suited to the hair of his head, reaching a little below his chin, and parting in the middle like a fork; his eyes are bright, clear and serene. He rebukes with majesty, counsels with mildness, and invites with the most tender and persuasive language. His whole address, whether in word or deed, is elegant, grave and strictly characteristic of so exalted a being! No man has seen him smile, but the whole world behold him weep frequently; and so persuasive are his tears, that the multitude cannot withhold their tears from joining in sympathy with him. He is very temperate, modest and wise. In short, whatever this phenomenon may turn out in the end, he seems at present a man of excellent beauty and divine perfections, every way surpassing the children of men."

LIME.—If any one doubts the paramount benefits of this article in any soil or situation, let him try half an acre, lime it well, and we think that in four or five years he will extend the application. One well done is forever done with this great fertilizer. Who ever saw the ruins of a house, where the plastering and mortar is found, but has seen the rich strong grass, at all seasons, wet and dry? What produces this?—The fertility that gathers to the residence of man cannot thus last. Can it be any other than the lime in the mortar? Lime acts more decisively upon some soils than upon others, but limestone land is ever fertile wherever found, and where it is deficient, if we add it, it will remain. It seems to act in the manures as a kind of condiment, preparing them for the appetites of the plants. A small portion of lime or alkaline matter is found in all vegetables, grasses and trees; lime supplies this, and hence the vigorous growth wherever it is found. It is much more advantageous to double the produce of one acre, than to work two acres for the same return. Let us try this article. If we see no marked advantage the first year, and but little the second, doubt not: for it requires time to get this material fairly under way. But when it does act, its operation is steady and durable, and annually returns the cost of the application.—*Farmer's Monthly Visitor.*

REMEDY FOR WHOOPING COUGH.—The Tennessee State Agriculturist says:—Take three cents worth of liquorice, three of rock candy, three of gum arabic, put them in a pan of water, simmer them till nearly dissolved, then add three cents worth of paragoric and a like quantity of antimonial wine. Let it cool and sip whenever the cough is troublesome, and the cure is said to be certain.

APPETITE—A relish bestowed upon the poorer classes, that they may like what they eat, while it is seldom enjoyed by the rich, because they may eat what they like.

AUGUSTA MARKET.

TUESDAY P. M., May 2.

Cotton.—Since our report of last Tuesday, the market has been very active, and the advance prices of the week ending 25th ult., have been fully sustained, if not improved upon. We now quote 5 to 7 cents as extremes of the market—principal sales 5½ to 6½ cents; remarking that the market closes firm with a good demand.

Exchange.—There is no change in the rate of Exchange, which continues at par. Central Bank bills range from 25 to 27 ℔ cent discount. Alabama 18 to 20 ℔ cent discount. State 6 ℔ cent Bonds 50 to 51½.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., MAY 10, 1843. No. 10.

MR. FOOTE'S PRIZE ESSAY.

[Continued from page 66.]

A FUNDAMENTAL PRINCIPLE.

What has now been advanced will make apparent, if the writer has not failed of his object, the importance of what he deems a very fundamental principle in the application of manures, viz: that not only in the quantity and kind, but in the mode of their application also, *manures should always be adapted to the peculiar character and condition of the soil.* This general principle, in its relation to the nutritive manures, may be reduced, by way of detail, to a number of highly practical rules, the most important of which are the following:

RULES FOR THE APPLICATION OF MANURES.

1. The smaller the quantity of organic matter in the soil, the greater should be the quantity of manure applied, and vice versa.

A light dressing of manure on an exhausted soil, and a heavy one on a soil already stored with nutritive matter, would be alike injudicious: the former being insufficient, not only to give a permanent fertility to the soil, but even to make the present crop a remunerating one, and the latter having no immediate office to perform—the crop to which it is given being already supplied with appropriate food.

2. The heavier, moister and colder the soil, the lighter, drier and warmer should be the manures applied; as horse and sheep dung in an unfermented state.

"Animal manures develope more or less heat, according to their nature and their state of fermentation; those which have not been decomposed excite more heat and maintain it for a longer time than others. The excrements of the horse and sheep are more heating in their action than those of the cow; the black or brown manures warm the soil more than marl or chalk." Chaptal, p. 37.

3. The lighter, drier and warmer the soil the heavier, moister and less heating may be the manures. The liability of light soils to suffer from drought, should lead the farmer, not only to exercise great care in selecting the most suitable manures, but to see that they are thoroughly incorporated with the soil, and not left in masses to increase the evil. Moderate quantities of either animal or vegetable matter, if properly blended with the soil, will promote its moisture, by increasing its power of absorption; but if applied in excess, or left in considerable masses, the opposite effect will be produced.—The same considerations should have their weight in relation to the kind and quantity of manure used (if any) in the hill, for hoed crops.

4. The more porous the soil, having a loose subsoil, the nearer the surface should the manures be deposited, to avoid infiltration.

We must beware, however, that while we draw one foot from the water, we do not thrust the other in the fire. If, on one hand, by placing our manures too deep in the soil, we suffer loss from infiltration, so, on the other, by leaving them upon the surface, we shall find ourselves losers by evaporation, though, perhaps to a less extent. The true practice would be to give them just that covering, which, while it would protect them from the more direct action of the atmosphere, would at the same time keep them longest within reach of the roots of the plants.

5. The more impervious the soil, having a compact subsoil, the deeper and more intimately should the manures be incorporated, to promote the freer action of the sun and air upon the soil, to render it easier of cultivation, to secure a wider range for the roots of the plants, and to prevent excessive moisture in wet, and drought in dry weather.

The common air, which is to a great extent excluded from soils of the kind now under consideration, exerts a most powerful agency in promoting vegetation, and that in various ways: 1. By imparting to the soil the temperature of the atmosphere; 2d. By furnishing nutritive principles from the decomposition of its own constituents; 3d. By serving as a medium for the introduction into the organs of plants their appropriate aliments; and 4th. By conveying to the roots of the plants, the various fertilizing matters contained in the dews which it deposites on the surface of the earth. Says Chaptal, (p. 33,) "That earth which is most easily affected by the dews, yields most readily to the action of the roots, whether it be to fix the plants firmly by their extension, or to draw from the soil its nutritive properties."

6. On soils disproportionately silicious, or calcareous, manures should be applied in combination with clay, or argillaceous loam, to increase the retentiveness of the soil, by giving it a stronger texture.

The presence of a certain degree of moisture which is not always possessed by soils of this description, is necessary, 1. To excite, by the oxygen which it contains, the vital energies of the plant; 2. By its solvent properties to aid in decomposing the vegetable matters in the soil, and 3. To dilute, to the requisite degree, the food thus prepared for the plants, and help convey it to their delicate organs. "It is generally considered," says Johnston, (Agricultural Chemistry, p. 78,) "that solid substances of every kind are unfit for being taken up by the organs of plants, and that only such as are in the liquid or gaseous state, can be absorbed by the minute vessels of which the cellular substances of the roots and leaves of the plants are composed.

7. On soils disproportionately argillaceous, manures should be applied in combination with silicious or calcareous matter, to increase its permeability and thus make it more friable, raise its temperature, and secure to a greater degree the beneficial influence of the atmosphere.

To be convinced of the importance of permeability, or looseness of texture to the soil, we need but reflect for a moment that plants are not permitted, like animals, to roam abroad in quest of their food, the invariable limits of their pasturage being the extremes of their roots. How obviously necessary then, that they should be enabled to extend their roots with the utmost freedom, and lay under contribution, without impediment, whatever elements can yield them subsistence.

8. On positively wet soil the application of manure should, in every case, be preceded by thorough draining.

"Whatever writer is converted into steam, the ascending vapor carries off much heat along with it. Let two adjoining fields be wet or moist in different degrees, that which is wettest will almost at all times give off the largest quantity of vapor, and will therefore be the coldest. What is the remedy? A removal of the excess of water? And how? By effectual draining. The first effect upon the soil is the same as if you were to place it in a warmer climate, and under a milder sky, where it could bring to maturity other fruits and yield more certain crops." Johnston, p. 54.

"If the water is withdrawn from a marsh, free access is given to the air, and the marsh becomes a fruitful meadow." Liebig, p. 116.

To the elevation of the temperature of cold, wet soils, too much importance can hardly be attached. "The solvent power of water over solid substances, is increased by an elevation of temperature. To this fact is ascribed, among other causes, the peculiar character of the vegetable products, as their extraordinary luxuriance, in tropical countries. Johnston, p. 48.

"Warmth renders the sap fluid, and quickens its circulation; cold thickens it and renders it stagnant. It is heat alone, that by animating the vegetable organs, enables the plant to elaborate within itself the nourishment which it receives." Chaptal, p. 36 and 102.

ADDITIONAL RULES.

The relation of manure to the *roots* of plants and the peculiar *action* of manures on different plants and on different classes of crops, give rise to the following additional rules.

9. The deeper the roots of any plant penetrate the earth, the deeper should the manures be deposited; and the more superficial the roots of any plant, the nearer the surface should they be lodged.

The *mouths* of plants being uniformly placed at the extremes of their roots, the necessity is obvious, that in order to derive from them the benefits intended, the substances employed as manure should be distributed in the soil, with some regard, at least, to the extension and position of these roots. That system which should lead the farmer to prepare in the same manner a patch of ground for strawberry plants, whose creeping roots scarce penetrate beneath the surface, and another for parsnips, which have been known to strike their roots to the perpendicular depth of six feet, would be indeed ridiculous.

10. The quantity and quality of manure should be carefully adapted to the character of the plant cultivated, as being a great or small consumer, and as having a special partiality for a particular constitution of soil, or for a particular kind of nutritive principles.

Some species of plants, as Indian corn, for instance, are well known to demand a supply of food which would surfeit and destroy the more delicate grains; some thrive luxuriantly in cold and wet, and others in warm and dry soils, to which an exchange of locality would prove fatal; and some, again, evince a natural appetite for the rank exhalations of fermenting manures, as those, in general, which have long tap roots, and large, fleshy stalks, while others prefer ammonia, as red and white clover; others lime, as potatoes and wheat; others common salt, as the asparagus plant, &c.

11. Whenever manure is furnished to the soil, the quantity applied should be amply sufficient to secure the fullest developement, and most vigorous growth of the plants intended to be cultivated.

It is a most interesting and important discovery of modern science, that plants, through the agency of their leaves, derive no small propor-

BOMMER'S MANURE.

The claims of Mr. George Bommer to the discovery of a process, by which masses of vegetable and other matter can be readily and cheaply converted into manure of the most fertilizing qualities, has attracted much attention in the agricultural world, for the last twelve months. We were disposed at first to ridicule it, as one of the numerous humbugs of the day; we never doubted the value, if we could have been assured of the authenticity, of the discovery. When, therefore, we were at the North last fall, and heard Mr. Bommer spoken of as a scientific gentleman, and any thing but the charlatan we had imagined him to be, we were induced to inquire farther into a subject which was likely to prove so interesting to our readers. We met with many who had purchased the right, and who anticipated the most beneficial results, but with none who had had an opportunity of reducing the experiment to practice.—After our return, attracted by various favorable notices in the northorn papers, we were requested frequently by our subscribers to ascertain the particulars of method, price, &c. Accordingly, we opened a correspondence with Mr. Bommer, the result of which is, that he has appointed us his agents for the State of Virginia, and we are now prepared to dispose of the right of using this invention, with full and particular directions, upon the terms indicated below.

Manure is the farmer's sheet anchor, and he who affords facilities, whereby its production may be increased, is certainly in a fair way to rival him "who caused two blades of grass to grow where only one grew before." But the increase of quantity is not all; the capability of getting up a pile of manure in a few days, just where it is wanted, presents advantages almost incalculable in its consequences. The foreign substances (by which we mean those that the farmer would have to purchase,) necessary to convert one thousand of straw into four thousand of manure, will not cost more than fifty cents.

We make the following extract from Mr. Bommer's statement with respect to his invention:—

"This invention is the fruit of many years of exertion and chemical labor, and the result of repeated and various experiments.

The secret of the invention to make the manure, is accurately described and specified in my method secured by patent. The preparation of said manure is very simple and easy, and every farmer, by following my method, can exactly count upon certain success.

We may, therefore, abandon for the future, the partial use and application of every kind of merely stimulating manure, such as lime, plaster of Paris, ashes, &c.

The merit of my method essentially consists in the following important points:

1. In being able to reduce in a short time all kinds of straw and ligneous weeds to a rich, unctuous and durable manure, such as wheat straw, barley, rye, buckwheat and other black grains; stalks of Indian corn, rice and other plants; dried or green potato tops, tops, leaves, stalks and roots of all kinds of plants; green or dried seeds, green rushes, sea weeds, sea rushes, heather broom, stubble, in fact, every thing belonging to the vegetable kingdom, and a great many other things lying about farms which are often allowed to go to waste. Even the ground itself may be converted into the best manure or compost.

2. In the combination or alliance of fecundating substances, the use of which when separated, would not and could not produce the desired effect.

3. In the production of a very considerable quantity of factious water, which, when combined with other ingredients, forming lees, furnishes the farmer with a fertilizing liquid, the commixture of which in either vegetable or mineral substances, gives a manure of the richest kind.

4. In the production of a quantity of nitrate of lime and caustic potash; of ammonia and saltpetre—four substances which modern chemistry has found to contain the most fecundating properties possible.

N. B. Nitrate of lime and caustic potash are formed by the mixture of ingredients composing the leese, as chemical analysis will easily demonstrate. Ammonia and saltpetre are produced by the lees combined with hydrogen and azote thrown off by the high fermentation of the mass. The existence of the first is made known to the senses by the strong smell of ammonia when the heap is opened.

From all this it is clear that my method, employed on farms, offers the following advantages:—

1. That those who have straw will be able to change the same into manure immediately after the crop is housed, or at any required time.—Those who have not straw may use any green or dry substance instead; and that those who have neither straw nor the substance above mentioned, may change the very soil itself into a very good earth manure, and in any spot they may choose.

2. That a farmer can make with the greatest ease, in a few days, earth manure, or compost, which will answer all the purposes of animal manure, and excel in their fecundating properties all other ordinary composts, which by other means can be had hardly in one year, more frequently only in three years. That this earth manure may be used in the spring to quicken the growth of seed that has suffered from the rigors of the winter; to manure wheat previously sown without manure; it will be a great benefit in planting Indian corn; for top dressing of artificial and other meadows; it is of the greatest use in gardens, mulberry and other fruit trees, keeping at once the ground moist and producing rapid vegetation.

3. That the farmer will have the advantage of being able to make his manure heaps when, where and as he pleases; he will be able to open them when they are in heat without losing any of the fecundating moisture.

4. By means of the lees, which this method will inform him how to make, it will be easy for him to give to his farm yard manure more invigorating properties, and he may increase its bulk at pleasure. Farm yard manure, in fact should be used only as the leaven to make the different heaps required.

5. By the great quantity of moisture entering into the materials, the weight of such of them as are dry, will be increased fourfold; that of the others is more than doubled.

6. This method enables the farmer to control entirely his manure heaps; that is to say, he will be able to make them in all their parts equally good and fertilizing. The lees, which distribute the saline and soluble particles in a regular and uniform manner, will produce an even crop throughout the field.

7. By the high degree of heat to which in that course of making it attains, the germinating power of all weeds found in the materials thus submitted to decomposition will be utterly destroyed. Hence manure made after after this method never re-produces weeds.

8. The farmer will also be able to graduate his manure. He may have it of any degree of strength he wishes. This will enable him to forward the growth of plants in a manner hitherto unknown.

9. By means of manure thus graduated at will, market gardeners will have their produce much earlier in the market than heretofore.—They will be able also to heat their hot-beds anew by means of the lees without disturbing the frames.

10. In fine, the leese by which the manure is made, are prepared cold and without any previous chemical preparation; the majority of the ingredients may be found at hand on almost every farm, and cost nothing; and water, which is the basis of the system, is of no more expense. All here concur to render the method truly economical. Such are the principal grounds on which the system is recommended.

My method rests solely upon facts which are the results of numerous experiments. I have explained it in simple terms, without making use of any technical expressions; it is as easy to understand as to put in practice. Thus clearly and simply detailed, I present it to the public, having proved, by repeated public experiments in presence of enlightened farmers, that all I have said is true, and that the advantages to be derived from its adoption are real and not visionary.

To conclude—as this method is my property, secured to me by patent, I hereby give notice, that the pamphlets of my "Method," are all signed in my own hand writing, and sealed, and can be obtained only of myself or my agents, authorized for this purpose, and that every method circulated or sold by any other persons, I declare false and counterfeit.

To facilitate the purchase of the Method, the price is fixed at the following exceedingly moderate rates:

For gardens of any extent	$6
For farms, under 200 acres	10
" " from 200 to 400 acres	15
" " over 400 acres	20
" plantations of any extent	25

For this small sum, the method becomes the property of the purchaser, for his own use forever.

The application of this system is very simple, and the process plainly explained in my method; but if any one of the purchasers should meet with any difficulty in its application, or should not realize the results that this method offers, they may apply to me for the instructions necessary in order to a complete success in the operation. If there should be a final failure, which has never yet occurred, the purchase money shall be restored.

GEORGE BOMMER.

The following commendatory notice of this valuable discovery, is from Professor Eli Ives, M. D., one of the Vice Presidents of the United States Agricultural Society:

"I have examined the pamphlet of Mr. Bommer on the subject of manufacturing manure. His method is founded on correct philosophical principles, agreeable to those recently advanced by Liebig. If the farmers can be induced to purchase the right, and thoroughly execute his plan of making manure, in my opinion, it will very much increase the value of their farms.

E. IVES.

The Connecticut Farmers' Gazette for December, published at New Haven, contains the following certificate:

"I hereby certify that, having made repeated trials of Mr. George Bommer's method of making manure by fermentation, and having tested its effects in the rapid decomposition of the mass to which it has been applied, and having also witnessed the influence of the manure made by this process, in promoting the growth of vegetation, I am prepared to regard the invention as an important accession to the farming interest; and, although, having tried other modes of making manure with varied success, I am free to acknowledge that I have never been acquainted with any system of the kind that would compare with this for utility.

ERASTUS DUDLEY.

The editor adds—"We are well acquainted with Mr. Dudley, the author of the above certificate, and we know him to be a man of sterling integrity. He is an intelligent farmer, and not likely to be imposed upon by every *new thing*. Inasmuch as he has tried Mr. Bommer's method, and gives his unqualified testimony in its favor, we have no hesitation in commending his statement to the confidence of the public."

Certificates from intelligent farmers might be greatly multiplied, but we consider them unnecessary.—*Southern Planter.*

WEDNESDAY, MAY 10, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

OUR ISSUE.

Since our commencement, which was two months later than we had at first designed, being the first of March instead of the first of January, we have issued the Cultivator weekly, instead of every two weeks, until we could make up the lost time, so as to have the volume close with the year. Having accomplished our object with the issue of the present number, it will, hereafter, be issued every other Wednesday, in strict accordance with the terms.

We avail ourself of this occasion to repeat our acknowledgments to our numerous friends, for the interest they have manifested in the extension of our circulation, and to re-assure them of our zeal in the enterprise, and now that we have got regularly under way, we hope to be able to render the succeeding numbers more interesting to the readers than those which have preceded.

We hope our friends will continue to give us the result of their experiments in every department, for we should be pleased to have each number well filled with communications.

CORRECTION.—In the article signed "Monticello" in our last, copied from the Columbia (S. C.) Planter, instead of "Kentucky *hemp*-grass," read "Kentucky *blue*-grass."

RECIPE FOR KILLING CATTERPILLARS

"Kill! kill! kill!"—*Shakspeare.*

The following advice to farmers, from the Gospel Banner, is sensible and to the point—The catterpillars may yet be destroyed, and no time should be lost in commencing and completing the work of destruction:

"This is to be a great year for catterpillars on fruit trees. The eggs were deposited on the limbs about the first of July last, when the weather was dry and warm, and afforded the parents a fine time to provide for a numerous progeny the [illegible] next year. If you will examine your apple trees you will find the limbs greatly infested with these eggs. Now is the time to destroy them. Do not leave the buds swell—But how shall this be done? By simple means. Just make a strong ley or soap suds strong enough to bear an egg, and with a common piece of cloth, wash the infested limbs. It will kill every mother's son of an egg, and you will find no catterpillars' beds upon them in May or June. Even without regard to catterpillars it is an excellent plan, every spring, to wash trees with strong soap suds. This will kill various sorts of insects in the egg—it will cleanse and renovate the bark, and promote the health and fruitfulness of the tree. Try it. Be not afraid of injuring the tree, even if the ley is so strong as to blister your hands. It will do no harm if applied before the buds are much swelled; but it will kill the young leaf.

INFLAMMATION IN THE EYE OF THE HORSE, &c.—A correspondent of the Albany Cultivator says: "I had a horse hurt his eye the past winter, and I thought he would lose it; but I have restored it again. For inflammation of the eye, take sassafras twigs of one year's growth; take the inner bark, a handful to a pint of cold water; let it stand for a few hours; it will become thick, like the white of an egg; wash the eye out well; it will remove the inflammation. For a film on the eye, take loaf sugar, pulverize it as fine as possible; take a goose quill and fill it, and blow it in the eye, which will remove it. My horse was entirely blind, and the above cured him, so that he can see as well as ever."

For the Southern Cultivator.

CULTURE OF SWEET POTATOES.

GREEN COUNTY, May 4, 1843.

MESSRS. JONES—I have noticed the plan of raising Sweet Potatoes by Mr. W. McKinley, of Lexington, Ga., published in the Cultivator, whose plan I am fully of the opinion is a good one.

I am, however, of opinion that the old plan of planting in ridges, could be made to produce as many bushels to the acre as the one proposed by Mr. McKinley, and much easier gathered, and I make this communication for the benefit of those who have planted in ridges, which I intend to adopt at the proper time, viz: after my potatoes come up well, I shall plough and hill them up, and then gather rotten straw or leaves from the woods, and fill up the space between the ridges, and put a sufficiency on the ridge to prevent the rays of the sun or wind from drying them. Nothing should show itself but the top of the plant. By this method, the space and the ridges will be kept in a moist and cool condition, and the potato vines will cover the whole surface. By this mode of culture, only one working is necessary, and will add a rich coat of manure for the next crop, and also prevent grass or weeds from springing up.

After I gather my growing crop, I will inform you of the result, and hope others will try it and do the same.

I will however state, that I have planted a few rows on Mr. McKinley's plan, in the same patch, and will fully test the mode of culture.

JOHN ROOT.

PUNCTUALITY.—Method is the very life of business—and there is no method without punctuality. Punctuality produces calmness of mind. A disorderly man is always in a hurry; he has no time to speak to you, because he is going elsewhere, and when he gets there, he is too late for his business; or he must hurry away to another before he can finish it. Punctuality gives weight to character. Such a man has never an appointment, and I know that he will keep it. This conviction secures punctuality to you; for like other virtuous propensities (such as truth, honesty, &c.) it becomes contagious. I owe you punctuality. If I have made an appointment with you, and have no right to throw over your time, it is by my own. Punctuality to engagements, is a saving virtue, and is one of the requisites to the character of a good member of the community.—*Selected.*

CUT WORMS

We annex, says the American Farmer, with feelings of pleasure, the following truly valuable communication from Dr. Samuel D. Martin upon the habits, nature and species of the cut-worms, and from our personal knowledge of the scientific and practical knowledge, the acute observation, and philosophic turn of mind of the writer, we are convinced that the means which he suggests for their destruction, are those the best adapted to that purpose. Farmers and planters, whose lands are infested with the cut worms will do well to bear in mind what the Doctor says upon the subject.

Last spring I collected some cut-worms and put them into a glass jar with a sufficiency of dirt, where I fed them until they rolled themselves up in mud balls. By cut-worms I mean a worm about an inch long of a grey color, that lives under the ground, and come out in the night, and dark cloudy days, and cut off a plant; eats part and then returns to drag the balance into the ground after it. When taken out of the ground he puts his head and tail together and rolls himself into a kidney shape. Those cut-worms, after going into the chrysalis state, produced a grey miller or moth, such as we frequently see about our candles in the summer time, and are called by us candle-flies.

I kept three of these millers in a jar, and they deposited their eggs upon some clover leaves and bloom that I put in the jar. On the 3d of June these eggs hatched little caterpillars or cut-worms. I fed them principally upon young clover leaves. I think there must have been several hundred; I did not count them. When they were nearly grown they became so voracious, and required the jar, which had been only three pints, to be filled so frequently that I killed all but three of them; these went up in mud balls on the 21st of July, came out millers, moths or candle-flies, as you may choose to call them, from the 5th to the 7th of August. Unfortunately all the moths were of one sex, so that I lost the breed: these I call the two-crop cut-worm.

Other cut-worms that I put up at the same time, that is, early in the spring, did not produce moths until the 11th or August: these were not quite as dark colored as the first. These I call the one crop cut-worm. This will reconcile the statements of two writers upon the subject, who have differed about the time the moth makes its appearance, the two crops each appearing at both times. I saw, also, the moth that produced the cut-worm telegraphed above in my clover field in October.

This moth is a night fly, and is rarely seen in the day time, unless forced from its resting places. From the attraction that fire has for this kind of butterfly, (permit me to call the moth a butterfly, in accordance with its common name) it is probable that fires kindled in our fields with brush and straw, of dark nights, will destroy a great number of them. Salt put on [illegible] might also destroy the worm; but the best remedy that I have ever tried is tally-ringing. This, by destroying the vegetation, kills the cut-worm by cutting off its supplies for food, and it also destroys the roots of the grass upon which the young worm would live during the winter. I have put no confidence in and by trying where I have had the ground ploughed in the fall or winter.

This moth that produces the cut-worm is the parent [illegible] of cut-worms. I have made experiments with the eggs you and grub-worm, but never [illegible] moth in the place of these. I will state what I found last year in the [illegible] all the other years and [illegible]—And it has been the case for [illegible] past, that they have done no more damage than any other insect except the [illegible] fly and grasshopper.

The cut-worm [illegible] attacks

ON THE ALTERNATION OF CROPS.

It has long since been found by experience, that the growth of annual plants is rendered imperfect, and their crops of fruit or herbs less abundant, by cultivating them in successive years on the same soil, and that, in spite of the loss of time, a greater quantity of grain is obtained when a field is allowed to lie uncultivated for a year. Durihg this interval of rest, the soil in a great measure, regains its original fertility.

It has been further observed, that certain plants, such as peas, clover, flax, thrive on the same soil only after a lapse of years; while others, such as hemp, tobacco, *helianthus tuberosus*, rye and oats, may be cultivated in close succession when proper manure is used. It has also been found, that several of these plants improve the soil, while others, and these are the most numerous, impoverish or exhaust it. Fallow turneps, cabbage, beets, spelt, summer and winter barley, rye and oats, are considered to belong to the class which impoverish a soil; while by wheat, hops, madder, late turneps, hemp, popies, teasel, flax, weld, and licorice, it is supposed to be entirely exhausted.

The excrements of man and animals have been employed from the earlist times for the purpose of increasing the fertility of soils; and it is completely established by all experience, that they restore certain constituents to the soil, which are removed with the roots, fruit or grain or entire plants grown upon it.

But it has been observed that the crops are not always abundant in proportion to the quantity of manure employed, even although it may have been of the most powerful kind; that the produce of many plants for example, diminishes in spite of the apparent replacement by manure of the substances removed from the soil, when they are cultivuted on the same field for several years in succession.

On the other hand it has been remarked, that a field which has become unfitted for a certain kind of plant, was not on that account unsuited for another; and upon this observation, a system of agriculture has been gradually founded, the principal object of which is to obtain the greatest possible produce with the least expense of manure.

Now it was deduced from all the foregoing facts, that plants require for their growth different constituent of soil, and it was very soon perceived, that an alteration of the plants cultivated maintained the fertility of a soil quite as well as leaving it at rest or fallow. It was evident that all plants must give back to the soil in which they grow different proportions of certain substances, which are capable of being used as food by a succeeding generation.

But agriculture has hitherto never sought aid from chemical principles, based on the knowledge of those substances which plants extract from the soils on which they grow, and of those restored to the soil by means of manure. The discovery of such principles will be the task of a future generation, for what can be expected from the present, which recoils with seeming distrust and aversion from all the means of assistance offered it by chemistry, and which does not understand the art of making a rational application of chemical discoveries? A future generation, however, will derive incalculable advantage from these means of help.

Of all the views which have been adopted regarding the cause of the favorable effects of the alternations of crops, that proposed by M. Decandolle alone deserves to be mentioned as resting on a firm basis.

Decandolle supposes that the roots of plants imbibe soluble matter of every kind from the soil, and thus necessarily absorb a number of substances which are not adapted to the purposes of nutrition, and must subsequently be expelled by the roots, and returned to the soil.—Now, as excrements cannot be assimulated by the plan which ejected them, the more of these matters which the soil contains, the more unfertile must it be for the plants of the same species. The excrementitious matters may, however, still be capable of assimilation by another kind of plant, which would thus remove them from the soil, and render it again fertile for the first. And if the plants last grown also expel substances from their roots, which can be appropriated as food by the former, they will improve the soil in two ways.

Now a great number of facts appear at first sight to give a high degree of probability to this view. Every gardner knows that a fruit tree cannot be made to grow on the same spot where another of the same species has stood; at least not until after a lapse of several years. Before new vine stocks are planted in a vineyard from which the old have been rooted out, other plants are cultivated on the soil for several years. In connexion with this it has been observed, that several plants thrive best when growing beside one another; and on the contrary, that others mutually prevent each other's development.—Whence it was concluded, that the beneficial influence in the former case depended on a mutual interchange of nutriment between the plants, and the injurious one in the latter on a poisonous action of the excrements of each on the other respectively.

A series of experiments by Macaire Princep gave great weight to this theory. He proved beyond all doubt, that many plants are capable of emitting extractive matter from their roots.—He found that the excretions were greater during the night than by day (?), and that the water in which plants of the family of the *Leguminosæ* grew acquired a brown color. Plants of the same species placed in water impregnated with these excrements, were impeded in their growth, and faded prematurely, while, on the contrary, corn plants grew vigorously in it; and the color of the water diminished sensibly; so it appeared that a certan quantity of the excrements of the *Leguminosæ* had already been absorbed by the corn plants. These experiments afforded, as their main result, that the characters and properties of the excrements of different species of plants are different from one another, and that some plants expel excrementitious matter of an acrid and resinous character; others mild substances resembling gum. The former of these, according to Macaire Princep, may be regarded as poisonous, the latter as nutritious.

The experiments of Macaire Princep afford positive proof that the roots, probably of all plants, expel matters, which cannot be converted in their organism either into woody fibre, starch, vegetable albumen, or gluten, since their expulsion indicates that they are quite unfitted for this purpose. But they cannot be considered as a confirmation of the theory of Decandolle, for they leave it quite undecided whether the substances were extracted from the soil, or formed by the plant itself from food received from another source. It is certain that the gummy and resinous excrements observed by Macaire Princep, could not have been contained in the soil; and as we know that the carbon of a soil is not diminished by culture, but on the contrary increased, we must conclude that all elements which contain carbon must be formed from the food obtained by the plants from the atmosphere. Now, these excrements are compounds, produced in consequence of the transformations of the food, and of the new forms which it assumes by entering into the composition of the various organs.

M. Decandolle's theory is properly a modification of an earlier hypothesis, which supposed that the roots of different plants extracted different nutritive substances from the soil, each plant selecting that which was exactly suited for its assimilation. According to this hypothesis, the matters incapable of assimilation are not extracted from the soil, while M. Decandolle considers that *they are returned* to it in the form of excrements. Both views explain how it happens, that after corn, corn cannot be raised to advantage, nor after peas, peas; but they do not explain how a field is improved by lying fallow, and this is in proportion to the care with which it is tilled and kept free from weeds; nor do they show how a soil gains carbonaceous matter by the cultivation of certain plants, such as lucerne and sainfoin.

Theoretical considerations on the process of nutrition, as well as the experience of all agriculturists, so beautifully illustrated by the experiments of Macaire Princep, leave no doubt that substances are excreted from the roots of plants, and that these matters form the means by which the carbon received from humus in the early period of their growth, is restored to the soil. But we may now inquire whether these excrements, in the state in which they are expelled, are capable of being employed as food by other plants.

The excrements of a carnivorous animal contain no constituent fitted for the nourishment of another of the same species; but it is possible that an herbivorous animal, a fish or a fowl might find in them undigested matters capable of being digested in their organism, from the very circumstance of their organs of digestion having a different structure. This is the only sense in which we can conceive that the excrements of one animal could yield matter adapted for the nutrition of another.

A number of substances contained in the food of animals, pass through their alimentary organs without change, and are expelled from the system; these are excrements, but not excretions. Now, a part of such excrementitious matter might be assimilated in passing through the digestive apparatus of another animal.—The organs of secretion form combinations, of which only the elements were contained in the food. The production of these new compounds is a consequence of the changes which the food undergoes in becoming chile and chyme, and of the further transformations to which these are subjected by entering into the composition of the organism. These matters, likewise, are eliminated in the excrements, which must therefore consist of two different kinds of substances, namely, of the indigestible constituents of the food, and of the new compounds formed by the vital process. The latter substances have been produced in consequence of the formation of fat, muscular fibre, cerebral and nervous substance, and are quite incapable of being converted into the same substances in any other animal organism.

Exactly similar conditions must subsist in the vital processes of plants. When substances, which are incapable of being employed in the nutrition of a plant, exist in the matter absorbed by its roots, they must be again returned to the soil. Such excrements might be serviceable, and even indispensable, to the existence of several other plants. But substances that are formed in a vegetable organism during the process of nutrition, which are produced, therefore, in consequence of the formation of woody fibre, starch, albumen, gum, acids, &c., cannot again serve in any other plants to form the same constituents of vegetables.

The consideration of these facts, enables us to distinguish the difference between the views of Decandolle and those of Macaire Princep. The substances which the former physiologist viewed as excrements, belonged to the soil; they were undigested matters, which although not adapted for the nutrition of one plant, might yet be indispensable to another. Those matters on the contrary, designated as excrements by Macaire Princep, could only in one form serve for the nutrition of vegetables. It is scarcely necessary to remark, that this excrementitious matter must undergo a change before another season. During autumn and winter, it begins to suffer a change from the influence of air and water; its putrefaction, and at length, by continued contact with the air, which tillage is the means of procuring, its decay are effected; and at the commencement of spring it has become converted, either in whole or in part, into a substance which supplies the place of humus, by being a constant source of carbonic acid.

The quickness with which this decay of the

excrements of plants proceeds, depends on the composition of the soil, and on its greater or less porosity. It will take place very quickly in a calcareous soil: for the power of organic excrements to attract oxygen and to putrefy is increased by contact with the alkaline constituents, and by the general porous nature of such kinds of soil, which freely permit the access of air. But it requires a longer time in heavy soils consisting of loam or clay.

The same plants can be cultivated with advantage on one soil after the second year, but in others, not until the fifth or ninth, merely on account of the change and destruction of the excrements, which have an injurious influence on the plants, being completed in the one in the second year; in the others, not until the ninth.

In some neighborhoods clover will not thrive till the sixth year, in others, not till the twelfth; flax in the second or third year. All this depends on the chemical nature of the soil, for it has been found by experience, that in those districts where the intervals at which the same plants can be cultivated with advantage are very long, the time cannot be shortened even by the use of the most powerful manures. The destruction of the peculiar excrements of one crop must have taken place before a new crop can be produced.

Flax, peas, clover and even potatoes, are plants, the excrements of which, in argillaceous soils, require the longer time for their conversion into humus; but it is evident that the use of alkalies and burnt lime, or even small quantities of ashes which have not been lixiviated, must enable a soil to permit the cultivation of the same plants in a much shorter time.

A soil lying fallow owes its earlier fertility, in part, to the destruction or convertion into humus of the excrements contained in it, which is effected during the fallow season, at the same time that the land is exposed to a further disintegration.

In the soils in the neighborhood of the Rhine and Nile, which contain much potash, and where crops can be obtained in close succession from the same field, the fallowing of the land is superseded by the inundation; the irrigation of meadows effects the same purpose. It is because the water of the rivers and streams contain oxygen in solution that it effects the most complete and rapid putrefaction of the excrements contained in the soil which it penetrates, and in which it is continually renewed. If it was the water alone which produced this effect, marshy meadows should be most fertile. Hence it is not sufficient in irrigating meadows to convert them into marshes, by covering, for several months, their surface with water, which is not renewed; for the advantage of irrigation consists principally in supplying oxygen to the roots of plants. The quantity of water necessary for this purpose, is very small, so that it is sufficient to cover the meadow with a very thin layer, if this be frequently renewed.—*Liebig.*

FAITH AND WORKS.—There is no pursuit in life in which the union of faith and works is more necessary, or productive of better effect, than in that of farming. This is well illustrated by the following little story, which we have somewhere heard or read. At the early settlement of New Hampshire, the inhabitants of a town in the interior consisted chiefly of Irish or Scotch Presbyterians, who among other things adopted the following custom. When their fields were planted and sown, the minister, with his elders, deacons and the farmers, visited each field in succession, offering up a short prayer at each, that their labors might result in a plentiful harvest. One day the procession engaged in this pious perambulation arrived at a field, where the minister stopped, took a quick but keen survey, and then addressed his flock to this purport: "My friends and brethren, we may pass along; it will be of no use to pray over this field, till there is more manure spread upon it; otherwise, even the prayer of a righteous man, however *fervent*, cannot be *effectual.—Alb. Cult.*

SALT IN AGRICULTURE.

Every farmer knows the beneficial effects of common salt, (Muriate of Soda,) in certain departments of agricultural economy. But the fact that so small quantities are used, is proof abundant, that ALL its good effects are not thoroughly understood And were they known and acknowledged, there would a question arise whether a full and general use of it would warrant the expense which its present prices necessarily involves.

We give our readers a few extracts on the benefit of salt in farming, from a work on that subject, published by C. W. Johnson, England.

Mr. Johnson speaks first of the farmers of Padstow Harbor, who annually bring 50,000 single horse cart loads of sea sand a distance of four or five miles, and spread it upon their land for the benefit the salt gives it.

In speaking of its benefits to wheat, he says: "Salt rarely causes the wheat plants to grow larger or taller, but fills up the ear better, and brings the feeble plant forward.

Sinclair says, "Salt appears to lessen the produce of straw and increase the weight of grain. Johnson recommends that salt be spread over the land some time before sowing, in quantities of not less than ten bushels or more than twenty bushels to the acre. He gives the following result of an experiment tried on light, gravelly soil.

No. 1. Soil without any manure for four years, gave 13 bushels, 26 lbs. per acre.

No. 2. Soil manured with stable dung to the previous crop, potatoes 26 bushels, 52 lbs. per acre.

No. 3. Soil with five bushels of salt per acre, and no other manure for four years, 26 bushels, 12 lbs. per acre.

An Essex (Eng.) farmer, Mr. Baynes, had his doubts of the value of salt removed by the following result; sandy, dry soil. Produce in bushels per acre:

Soil dressed with 15 loads of stable dung per acre, 17½ bushels.

Soil dressed with 14 bushels of salt per acre, immediately after the seed was sown, 36½ bush.

Mr. Johnson recommends the application of salt as a remedy for smut, blight and mildew, by the following process. Take one pound of salt to a gallon of water and throw it over the plants with a brush.

For barley, Mr. Ransome of Suffolk county, gives the following result:

Soil without any manure, 30 bushels per acre.

Soil dressed with 16 bushels of salt per acre, in March, gave 51 bushels per acre. A light sandy soil.

Turneps, Mangel, Wertzel, &c.—An experiment is reported by Sir Thomas Ackand of Devonshire, and another from Mr. Hares of Buckinghamshire, which though not so specific in results, are commendatory of it for these crops, if the soil is light and sandy. In clayey soils they found no good benefit.

Mr. Johnson recommends the application "of from ten to twenty bushels of salt to the acre for potatoes, to be spread on the surface as soon as the potatoes are planted, or ten bushels the previous fall and ten after planting."

He gives the following results of experiments with potatoes, on a light, gravelly soil. Produce in bushels per acre.

No. 1. Soil without any manure, 120.

2. Soil manured with twenty bushels of salt the previous September, 192.

3. Soil manured with stable dung at the time of planting, 218.

4. Soil manured with stable dung and 20 bushels of salt, 234.

5. Soil manured with 40 bushels of salt alone, 20th September previous, and 20 immediately after planting, 192½.

6. Soil manured with 40 bushels of salt, as in last experiment, and also with stable dung, 244.

Rev. E. Cartwright of Tunbridge, gives a similar result to his experiments, and says, "of ten different manures, most of which are of known and acknowledged efficacy, salt, with one exception, is superior to them all. In speaking upon its efficacy upon live stock, he quotes Mr. Curwen, M. P. of Cumberland, who deals it out in the following measure:

For Horses	6	ounces per day.
Milch Cows	4	" "
Feeding Oxen	6	" "
Yearling	3	" "
Calves	1	" "
Sheep	2 to 4	" per week.

"If kept on dry pasture or fed on turneps, give it without stint. It is supposed that if sheep have a regular supply of it, they will never be affected by the rot. Mr. Butcher for years employed salt for his cattle and sheep, on his farm in Norfolk. One of his fields was so unfavorable to sheep before he used salt, that he lost ten or twelve in a night, when feeding on the turneps, but after he adopted salt he never lost one. He gave his sheep salt without stint; but remarked that they always used *four times* the salt on this particular field, than when on any other on the farm. This field was one year rented to a neighbor who did not use salt. After losing ten sheep the first night, the tenant gave up the field in despair."

On a garden of sandy soil, owned by Mr. George Johnson, the following experiments were tried, with the results attached.

Windson Beans.—Produce in bushels per acre:

1. Soil without any manure, 135½.
2. Soil dressed with 20 bushels of salt per acre, week before seed time, 217.

Onions.—Produce per acre:

1. Soil manured with 20 bushels of salt and 10 tons of farmyard manure,

	Tons.	cwt.	qrs.	lbs.
	3	12	3	12
2. Soil manured with 12 tons of farm yard manure	2	10	2	19

Carrots.—Produce per acre:

1. Soil manured with 20 bushels of salt and 20 tons of manure	23	6	1	18
2. Soil 20 tons of manure only	22	18	0	26
3. Soil manured with 20 bushels of salt only	18	2	0	00
4. Soil without manure	13	4	0	00

Parsnips.—Produce per acre:

1. Yard manure, 20, salt twenty bushels	6	15	0	00
2. Yard manure, 20 tons	5	11	0	00

Early Potatoes.—Soil without any manure, 308 bushels.

Soil manured with 27 bushels of salt per acre, 584 bushels.

In conclusion, Mr. Johnson says, "if I wished to improve a soil of what is termed an old, worn-out garden, exhausted by fifty years cropping or more, I would give it (½ or a ¼ part at a time,) a good dressing of lime in the autumn, spreading it as soon as it is slacked, and forking it immediately. I would a week or two after that, dig and trench it well in the rough, and lay it up for the frost to act upon; and then in the spring, I would give it a good dressing of salt, (not less than six bushels to the acre.) The good effect of such a treatment would be manifest for two or three years after."

Let the American farmer remember, that we give the above sketches as the experimental results of an English cultivator, and in no way responsible for the success thereof attending, as in all cases sure in our climate, still we have no doubt, indeed we *know*, from actual experiment, that its value in agriculture is very great here, more, to be sure, on some soils and with some crops than with others. Thus, with wheat, we believe it highly valuable, while with corn, we should think it worse than nothing. For flax it has a good effect, also for tubeous and bulbous plants. How much further its use extends, we are not prepared to say, but doubt not that for our grasses, fruit orchards and gardens, it would, under a favorable state of things, be highly beneficial.—*Berkshire Farmer.*

tion of their elementary substances from the atmosphere; and that this proportion is graduated, to a greater or less extent, by the quantity, strength and vigor of their foliage. "Hence, the proportion of organic matter derived from the air, in any crop we reap, must always be the greater, the more rapid its general vegetation has been."

In illustration of the extent to which the atmosphere is drawn upon by plants for their nourishment, as well as the agency which manures exert in the operation, "Sprengel states, that it has been very frequently observed in Holstein, that if, on an extent of level ground sown with corn, some parts of a field marled, and others left unmarled, the corn on the latter portions grow less luxuriantly and will yield a poorer crop than if the whole had been unmarled."—Ib.

12. Unfermented manures should be appropriated, in general, to the use of hoed crops, fermented manures and composts alone, to the finer grains and grasses.

The reasons for this rule (which have been, in a measure, already anticipated,) are, that while Indian corn, potatoes and most tap root plants are benefitted, in the highest degree, by the powerful gases thrown off from manures undergoing fermentation, their effect upon the finer grains is, to hasten unduly the growth of the straw, and thus to expose the crop to the very serious evils of lodging, blasting, &c. "The plant," in this case, "absorbs more nourishment than it can readily digest, and becomes affected by a kind of obesity; the texture of its organs is rendered soft, loose and spongy, and unable to give their products the due degree of consistency." Chaptal, p. 76.

FERMENTATION OF MANURES.

That manure should never be suffered to undergo fermentation any where else than *in the soil*, or in well protected compost beds, may be argued from the facts, 1st. That even an incipient fermentation cannot take place without the evolution and escape of some of its volatile products, such as carbonic acid and ammonia, to the latter of which all nutrative manures are indebted for their principal efficacy; 2. That during fermentation (in the open air,) it is constantly exposed to further loss by infiltration and drainage; and 3. That the finer grains do not require this process to be undergone in the barn yard, since, coming as they mostly do, and as perhaps they always should, after hoed crops, they find the manure employed for the previous crop in just the requisite state of decomposition; a clear gain of the entire advantage secured in the previous harvest.

It may be objected to this view of the subject, that fermented manure is in particular cases indispensible for forcing vegetation—i. e. for hastening the growth and maturity of certain plants. Let this be admitted: still the admission does not establish the necessity of that waste against which we are protesting. Let the manure fermented, be carefully collected in compost heaps and we are satisfied.

APPLYING MANURES TO THE SURFACE.

Whether putrescent manures should ever be applied to the surface of the soil, is a question on which the opinions of distinguished agriculturists are far from being unanimous. The right decision of the question depends, in our view, upon the following circumstances:

1. The condition of the manure to be applied;

2. The character of the soil for which it is intended;

3. The nature of the crop to be benefitted by it; and

4. The time of the year when the manure is to be carried out.

1. If the manure to be applied has been composted, or if the process of fermentation has already spent its force upon it, there can be no serious objection to its being spread upon the surface; since the gaseous exhalations having already escaped, it is chiefly secured from the ravages of the atmosphere, and from infiltration, there is nothing to fear, as that is the very process best adapted to bring the decomposed particles in contact with the mouth of the plants which are to feed upon it.

2. If the soil for which the manure is intended be very porous to a considerable depth, the nearer the surface it can be deposited, without too much exposure to the atmosphere, the better, it being evident that the nutrative juices will soon descend beyond the reach of the plants, if it be in the first place buried too deep.

3. If the crops to be benefited consist of any of the finer grains or grasses, the application of the manure to the surface (harrowed in, in the case of grain,) will have a greater present effect than any other mode of application, as the roots, i. e. the mouths of the plants, lying close to the surface, will have the readier access to their food. That natural meadow land can thus be made to yield a greater burden of grass than by any other means, scarcely admit of a doubt.

4. If the manure to be applied is summer made manure, which must be carted out in the fall, this mode of application will have another argument in its favor. By being spread at this season of the year, after the heats of summer are past, the fermentation and evaporation will be but slight, and the rains and snows which may be expected to fall upon it in succeeding months will either wash it into the soil, or so imbed it among the roots of the growing crop, as quite effectually to shield it from the wasting action of the atmosphere the succeeding season.

One thought more upon this subject. With the relations of plants to the atmosphere as a source of nutriment, we are as yet much less acquainted than with those which they sustain to the soil; and agricultural science, in its onward progress may yet develope the fact, that manures applied to the surface, by exerting a direct and powerful agency upon the leaves of plants, and thus promoting an increased absorption of the nutritive particles of the atmosphere, may prove more beneficial, especially in the case of grasses and the finer grains, notwithstanding the losses they sustain from evaporation, than they would if buried beneath any portion of the soil.

GREEN CROPS FOR MANURE.

Green crops, ploughed under for the purpose of enriching the soil, have been regarded from very ancient times, as valuable aids in agriculture, and are still recommended in no small degree, by the highest agricultural authorities. It is indeed unquestionable, that a crop of clover, for instance, turned under the soil, will afford a sufficient quantity of nutriment for a crop of wheat or rye, and also leave the soil (if not cross-ploughed) in a condition highly favorable to the growth of such a crop. The great question is, whether it would not be more advantageous to the farmer first to give his cattle the benefit of the clover, and then turn under the remaining vegetable, together with the animal matter distributed over the soil, and thus secure two valuable objects instead of one. That such was the opinion of the late Judge Buel, (a more judicious adviser than whom has never contributed to the improvement of American farming,) will appear from his Cultivator, Vol. 2, p. 13 Vegetable matter when thus covered by the soil in its green and succulent state, readily undergoes decomposition, and forms a very enriching substance. The practice, however, is chiefly suited to the warmer countries where vegetation is rapid, and even there it argues a somewhat low state of the art, and is not the best way of producing decomposing matter.—When we are able to raise green food of any kind, it is better that we apply it in the first place to the feeding of animals, for then it not only yields manure, but performs another and not less useful purpose.

It is a consideration, notwithstanding, of some weight, that in case of feeding off the green crop, the nutritive substances lose somewhat by exposure and are much less evenly distributed over the soil for the cultivated crop. "When, however," continues the judge, "the practice is for any reason adopted, the period at which the plants should be ploughed down, is just when they are coming in flower, for they then contain the greatest quantity of readily soluble matter, and have the least exhausted the nutritive substance of the soil."

In the concluding clause of the extract last quoted, green crops are spoken of as "exhausting the nutritive substance of the soil." We take the occasion from this hint to raise an interesting inquiry. If the green crop, while growing above ground, *exhausts* the soil, and this must be admitted, how can it, by turning under, *enrich* the soil? Can it *give* to the soil anything which it has not first *taken away* from it? Science answers in the affirmative. By the aid of her light it has been discovered that plants derive a greater or less proportion of their constituent principles from the *atmosphere*. These principles, by the process of turning under green crops, become a constituent portion of the *soil*. This, then, is one of the secrets of their utility. It is not however the only one.—The *physical* condition of the soil is also improved by their means; its lightness, warmth and *power of absorption* are increased, so that still further draughts are made upon the atmosphere and thus the soil is permanently benefited.

Whether the crop "should be ploughed down just when coming in flower," or not till after maturity, is yet a question of debate, says Dr. Dana, p. 214. Powerful as are the effects of green crops ploughed in, it is the experience of some practical men, that one crop allowed to perfect itself and die where it grew and then turned in dry, is superior to three turned in green. The whole result is explained by the fact that dry plants give more gains than green Green plants ferment—dry plants decay. A large portion escapes in fermentation as gas, and more volatile products are formed than during decay."

The testimony of Chaptal hangs quite on the other end of the beam. "It is well known to the farmer," he remarks, "that ploughing in a green crop of any kind whatever, prepares the soil for producing well without any other manure; since, by this process, all that the soil has yielded is returned to it, with some additions resulting from the decomposed principles of air and water, which are contained in the plants."

"In order fully to understand this doctrine, which appears to me of great importance to agriculture, it is necessary to consider the successive changes which take place in annual plants during their growth; first, they produce green leaves, which, by coming in contact with the air, receive from it the principles of which I have spoken: subsequently the stalks increase in size and number, and are covered with numerous leaves, which absorb from the atmosphere a degree of nourishment suited to the increased wants of the plants. This state continues till after the period of flowering, when a change, worthy of note, takes place; the roots dry up, the stalks wither and change their color, and when frutification is at length completed, both roots and stalks have become mere skeletons, which answer but little purpose either for nourishing animals or manuring earth." p. 94.

But whether turned in green or dry, the plowing should not be so deep as wholly to exclude the action of the sun and air, (for acids will then be formed in the soil,) neither should cross ploughing ever succeed, as this would defeat the object intended by feeding the atmosphere instead of the soil, upon the virtues of the crop.

MANUFACTURED MANURES.

Certain manufactured substances, as bone dust, urate, poudrette, &c. might here receive a passing notice; but as they are not likely, at present, to secure much patronage among us, and certainly *should not be employed*, expensive as they are, until we have learned to save the *half of our home-made manures which is now suffered*

to be lost for want of a little attention, it is not deemed important to enter on any discussion of their merits; especially as these, together with the proper modes of applying them, are fully set forth in all our agricultural journals. We proceed, therefore, to our second division, viz:

STIMULATING MANURES.

The value of this class of manures depends, not so much on any direct impartation of food to plants, as on their agency in exciting their organs to greater activity, in appropriating to their benefit the influences of the atmosphere, in combating their insect enemies, and in dissolving the salts, neutralizing the acids, and improving the texture of the soil: as lime, marl, gypsum, ashes, saltpetre, charcoal, soot, sand, clay, &c.

LIME.

Lime has been long and extensively employed in Europe as a fertilizer of the soil, and with such success as to induce an English writer of note (Morton on Soils,) to assert, that "the majority of soils cannot be cultivated to advantage till they are dressed with lime; and whether considered as an alternative, as a stimulent, or as a manure, it will be found to be the basis of good husbandry, and of more use than all other manures put together. Whenever lime has been properly applied, it has been constantly found to prove as much superior to dung, as dung is to the rakings of the roads, or the produce of a peat mine." And says M. Puvis, a distinguished French author, "In limed earth, weeds and insects disappear. The earth if too light acquires stiffness, and is lightened if too clayey. In the same soils, with the same manure and the same tillage, by the addition to the ploughed layer of only one-thousandth part of lime, the products whether volatile or fixed, are increased in a wonderful manner; the soil of the lowest quality reaches the product of the second—the second rises one-half or more—and that of the best soil increases a fourth." Yet, strange as it may seem, there exists even among English agriculturists the greatest diversity of opinion in regard to the propriety and mode of its application on different soils, and the admission is heard on every hand, that extensive tracts of British soil have been rendered infertile by its use.

Were we to hazard an opinion on a subject regarding which not only learned farmers but "learned doctors disagree," we should say that the truth in the case was something like the following. Vegetable matter becomes the food of plants only in a state of decomposition; of this process lime is a powerful promoter; when, therefore, lime is incorporated with a soil containing much undecomposed vegetable matter, it rapidly prepares this matter for the use of plants; the immediate consequence is a great increase of vegetable products. But just in proportion to the crop produced, is the greatness of the draught upon the soil. Persisting, therefore, in the application alone of this mere exciting, *stimulating his soil to an unnatural activity, without supplying those nutrative substances which alone can sustain its strength*, the farmer finds, ere long, to his cost, that he has "overdriven his beast,"—that he has tasked his soil beyond its capabilities, and is fast reducing it to a state of exhaustion. During the early period of his experiments, while reaping his unwonted harvests, he could not sufficiently *extol*—now that he has closed the series and looks upon his jaded lands, he cannot enough *decry* the use of lime.

Such is, we apprehend, the origin, to a great extent, of that diversity of opinion which exists in regard to the *utility* of lime. Were its application always judicious, and accompanied, when necessary, with an adequate supply of nutritive matters, the probability is that no such disagreement would exist. Without, however, attempting to reconcile the multifareous and conflicting theories in relation to the use of this substance, we will proceed to notice some of the most obvious modes of its action, and leave the intelligent farmer to produce from his own experiments, (for here experiments are best indespensable,) the practice adapted to his particular soil. We observe, then,

1. Lime acts as a *specific food* for certain plants; i. e. it enters as a natural element into the composition of their substances, so that without its presence they cannot be grown to perfection. For the production, therefore, of these plants, (as potatoes and wheat, for instance,) the existence of lime in the soil is absolutely necessary. Whether any given portion of soil is destitute of this earth or not—and upon that depends entirely the propriety of its application as a *nutritive* substance—can only be determined by analysis.

2. Lime has great efficiency in *hastening the decay* of animal and vegetable matters. This is the secret of its efficacy when applied to old, matted turfs, to all peaty soils, and to such lands of whatever description as abound in undecomposed vegetable matter. To vegetable matter in a soluble state, and to animal matters in general, being easy of decomposition, it is not deemed proper to apply this substance, its tendency being, according to Chaptal, to form insoluble compounds, with almost all animal and vegetable substances that are soft, and thus to destroy their fermentative properties. Loudon also maintains that "lime should never be applied with animal manures, unless they be too rich, [?] or for the purpose of preventing noxious effluvia; and that it is injurious when mixed with any common dung, and tends to render the extracive matter insoluble."

3. Lime has the property of neutralizing any noxious vegetable acids, or metalic salts existing in the soil; which properly indicates the fitness of its application on fields infested with sorrel, on some marshy lands, (previously drained,) and on soils previously impregnated with the oxide of iron, or coperas.

4. Lime acts as an *alternative*, on both silicious and argillaceous soils, by the effect it has of giving greater adhesiveness to the particles of the former, and of diminishing the tenacity and compactness of the latter. To sandy lands, however, it should not be applied too liberally, as, if dealt out in large quantities, it will have the effect to form a kind of morter with the soil, and thus prove detrimental both to tillage and to vegetation. "Clay land bears this species of amelioration better than lighter soils. It powerfully assists all adhesive soils; and when laid on hot from the kiln upon deep clay, has been known to occasion a very great increase in the former crops."—*British Husbandry.*

5. From its cautic properties, lime is a valuable assistant to the farmer in combating those numerous insect enemies which so often ruin his hopes by depredating upon his fruit trees, his grasses, and his cultivated crops. How far he may be able to avail himself of its aid in this respect, is only to be determined by a careful series of experiments.

Finally, in the language of the work last quoted, "It is much to be regretted that some more definite judgment has not been framed regarding the properties of lime, the effects of which are exposed to the most contradictory results;" and some caution will be necessary in whatever trials may be made of it as a manure. It would be better that experiments on a small scale should precede the application of it on lands where its efficacy has not yet been proved. The quantity applied in general practice, to the acre, varies from 20 to 30 or 100 bushels, or even more, according to the character and circumstances of the soil, (the lighter and poorer the soil, and the more it has been limed, the less the quantity,) and this dressing is repeated once in four or five years, care being taken to recruit occasionally the nutrative matters in the soil, without the co-operation of which, by unanimous consent, the former substance would be worse than useless. When employed without regard to its caustic properties, it should be slacked, and then spread evenly over the surface, and if the ground be intended for cultivation, it should be exposed for several months before it is ploughed under. The effect will not commonly manifest itself before the second or third year.

[To be continued.]

MANUFACTURE OF SILK IN THE AUBURN PRISON, NEW YORK.

As the subject of manufacturing Silk in one of the New York State Prisons, has been a matter of some interest to the public a year or two past, it will assuredly be acceptible to our readers to learn how the establishment is progressing. In the New York Tribune, of Feb. 10th, 1843, we find a complete report of the superintendent, by H. Polhemus Esq., to the inspectors of the prison. Were not the document so lengthy we would be pleased to lay the whole of it before our readers, but as it is, we must let extracts suffice.

The manufacture of Silk was commenced on the 20th of May 1841, at the suggestion of the Governor. Two convicts, without experience, were put to the work on a small twisting machine. At the end of six months machinery was built in the prison, and eight convicts added to the two operatives. During the year 1842 a steam engine was employed in the establishment, and some forty hands gave themselves to the work. From the 20th of May, 1841, to the 1st of Feb. 1843, the manufactured articles amounted to $12,763 26. The agent says he has "no hesitation in declaring, that the business may be conveniently enlarged, during the present year so as to increase the force employed to 100 hands with an increase of profits exceeding 40 per cent and that it may be so extended as ultimately to employ all the convict labor."

"The agent, therefore, feels himself authorized to congratulate the inspectors on the successful introduction of a new, most interesting and most useful department of industry, which can be rendered at least as profitable as other modes of employing the convicts."

This, we have no idea is an exaggerated report for speculative purposes; for the agent only affirms that this business will as well repay for the labor as other employments. This is all we want. We desire to see no patent plans to wealth, but let it be fully understood that feeding silk worms, and reeling cocoons will pay as well as either mechanical or agricultural employments, and many may be induced to embark in this vocation. This is the time of the year to put out our orchards and make other arrangements for the silk culture, and we ask our friends not to despair—silk will be grown and manufactured in the United States beyond doubt. T. F.

GLAUBER SALTS FOR SWINE.—I have made some experiments on hogs, which were very satisfactory to myself. One day as I was returning from a store, with a paper of glauber salts, I thought I would go and take a look at my hogs. It was in the evening, just before they were fed. While I was looking at them, the paper happened to burst, and the salts fell upon the ground. The hogs devoured them greedily. I thought I would try giving them some regularly for a week, and see what effect it would have upon them. They appeared more brisk and frolicsome, and I observed at the end of the week, that they increased rapidly in weight to what they did formerly. They were then but six months old, and in about two months they weighed 350 lbs., and judging from appearances, I should think they did not weigh more than 200 before I gave them the salts. I observed it made their necks very thick, their hind legs grew larger than their fore legs, and several hogs that were before black, became nearly white, and they all appeared to thrive well.

WM. LARKIN.
Albany Cultivator.

They are few indeed who know how to be idle and innocent.

lar, and get their growth in the summer time in less than a month. Cold weather retards their growth, and those that are hatched in the fall remain in a torpid state during the winter, and get their growth slowly in the spring, at which time they do us the principal damage in cutting off the young corn and other young vegetables. Though they remain in a torpid state during the winter, they require food as soon as the weather gets warm in the spring, and if the vegetation has been all destroyed by fall or winter ploughing, which is rarely the case, they must starve. But I suppose it is not so much on his account as the turning up the ground and destroying their coverts, which allows the frost and wet to affect them. SAM'L. D. MARTIN.

COLIC IN THE HORSE.

There are few diseases more troublesome or dangerous to the horse than the colic; and it is usually in the winter that its appearance is most frequent. One of the best descriptions of the disease and its mode of treatment, is to be found in Steward's Stable Economy, from which we have condensed the following:

"The horse is usually attacked by the colic suddenly. In the stable, he paws the ground with his fore feet, lies down, rolls, sometimes quite over, lies on his back, but at times, when the distension of the belly is not great, will sometimes lie still for several minutes. When the distension is great, he neither lies or stands still a minute, but lies down and gets up incessantly, strikes his belly with his hind feet, and looks wistfully at his flanks. When standing, he makes many and fruitless attempts to urinate, and the keeper or owner generally imagines there is something wrong with the water."—Sometimes in the worst cases the swelling is very inconsiderable; but in all cases, as the disease proceeds, the pain becomes more and more intense; the horse dashes himself about with frightful violence; the perspiration runs off him in streams; his countenance betrays excessive agony, and his contortions are not suspended for a moment.

Sometimes he is attacked on the road. "If his pace is fast, he should be stopped at once. To push him on beyond a walk, even for a short distance, is certain death. The bowels are displaced, twisted and strangulated, partly by the distension, but aided a great deal by the exertion, and no medicine will restore them to their proper position." When death ensues, the bowels are found inflamed, twisted, and generally ruptured.

In the treatment of colic, the first object is to arrest the fermentation that is the primary cause, and re-establish the digestive powers.—"In mild cases, a good domestic remedy, in common use among old fashioned people, who have never heard of inflamed, spasmed or strangulated bowels, is whiskey and pepper, or gin and pepper. About half a tumbler of spirits, with a teaspoontul of pepper, given in a quart of milk or warm water, will often afford immediate relief. If the pain do not abate in twenty or thirty minutes, repeat the dose. Four ounces of spirits of turpentine, with twice as much sweet oil, is much stronger; but if the horse is much averse to the medicine, turpentine is not always safe."

"There is, however, a better remedy, which should always be in readiness wherever several draft horses are kept. Take a quart of brandy, add to it four ounces of sweet spirits of nitre, and three ounces of cloves. In eight days this mixture or tincture is ready for use; the cloves may still remain in the bottle, but they are not to be given. Set the bottle by, and label it distinctly, "Colic Tincture." The dose is six ounces, to be given in a quart of milk or warm water, every fifteen or twenty minutes, till the horse is cured. Keep his head straight and not too high when it is given. Do not pull out his tongue, as some stupid people do when giving a drink. Give him room, and if he will not stand till the drink be given, watch him when down, and give it, though he be lying, whenever you can get him to take a mouthful; but give the dose as quickly as possible. After that, rub the body with a soft wisp, walk the horse about *very slowly*, or give him a good bed and room to roll. In eight cases out of nine, this treatment will succeed, provided the medicine be got down the horse's throat before his bowels become inflamed, or strangulated or burst. The delay of half an hour may be fatal. When the second dose does not produce the relief desired, the third may be of double or treble quantity. I have given a full quart in about an hour, but the horse was very ill."

Bottles are generally used for giving medicine to horses, but unless the neck is wound with twine, there is danger of the horse breaking it with his teeth, and injuring himself with the pieces. A large horn, with a small point for insertion in the mouth, is preferred by many, as exempt from this danger.—*Albany Cultivator.*

SWEET POTATOES FOR HOGS.—It is generally admitted, that our sweet potatoes constitute an excellent article of food for hogs, and it is well known too, that few plants yield a greater amount of nutritious matter to the acre. Heretofore, however, planters have generally neglected to avail themselves of the advantages of this crop for their stock. It is true, if the potatoes are to be dug and thrown to the hogs, the planter loses much valuable labor from his crop, at a very important season. But this is not necessary; by making the potatoe patch long and narrow, (say a half or a fourth acre wide,) and a few hours labor once a week in running a cross fence, a stock of hogs may be kept fat from the first of August until the pea fields are open, with very little expense. For example, let him run a low fence across, so as to cut off a small portion of the patch and turn his hogs on this. While they are consuming the vines and roots on this portion, the potatoes in the other part are still growing undisturbed. When this portion has been eaten out entirely, let the planter have his cross-fence moved up a little farther, and thus give his hogs access to a fresh portion of the potato field. This plant, we think, commends itself to the attention of planters on several accounts. The cheapness of the food; its being ready for use at an important season for pushing forward young hogs, (and nearly every Southern planter kills his hogs young,) the greater amount of pork it enables him to raise, and the less corn it requires in the fall to make his hogs fully fat. And we may add to these, that every hog is thus made to gather his own harvest. The cheapness of this article of food, (when the labor of harvesting is saved,) certainly cannot be questioned. For from two to four hundred bushels of roots, besides the vines, per acre, is no small amount of nutritious matter for the labor bestowed in culture. If any one needs to be convinced that August is an important month for pushing forward hogs that are to be killed in the fall, let him try to fatten a very poor hog—he will eat more than his bacon will be worth. And, in fact, a year old that has been kept poor until the pea fields are open, will yield very little bacon. This plan enables the planter to keep his hogs fat and growing rapidly from the first of August until killing time. For by the time the potatoes are fully eaten out, the pea fields may be opened, and by the time they are done and the hogs confined ten days on corn, to harden the fat, the weather will probably be cold enough to kill. And here another advantage is gained. For the most successful curers of bacon we know, all agree that the earlier you can kill your hogs, the surer you are to have your bacon free from bugs in the summer.—*Planter.*

TO KILL LICE ON ANIMALS.—"Take the water in which potatoes have been boiled and rub it over the skin. The lice will die within two hours. I have used ten kinds of the strongest poisons to kill lice, all with effect, but none so perfect as this."—*Central N. Y. Farmer.*

HORTICULTURE, the attendant and embellisher of agriculture, which provides so many palatable and healthful additions to the substantial produce of the field, and correctors of the undue stimulus and acrimony of much animal food, merits all the fostering care which an uncorrupted and yet educated and refined taste has ever extended to it. A well cultivated garden, in due alternation of vegetable, fruit and flower, gives us poetry without its illusions—nature divested of her ruggedness, and art of its constraint —*Dr. Bell.*

CULTIVATION OF SILK.—We have been informed that East Baton Rouge is soon to become the seat of a regular silk plantation, whereby the most ample test will be given to the project of making this article one of the staples of the State. A gentleman named Vasseur, just arrived from France, has purchased land, and is making rapid arrangements to commence the business, in which he has the experience of many years.—*Baton Rouge Gazette.*

As spring, with its cheering sunshine, and refreshing showers, reanimates to new life the growth of vegetation; so the soothing accents of love and sympathy restore to wonted brightness the heart desolated by grief; causing it to put forth the shoots of gratitude and joy.

Fragments of Time.

A good temper, a good library, good health, and a good wife, are four choice blessings.

AUGUSTA MARKET.

TUESDAY P. M., May 9.

Cotton—Our market continues animated, and sales to a considerable extent have been made during the week, at prices fully sustaining the advance we have heretofore reported, and the market closes firm. We quote 4¾ @ 7 cents as the extremes of the market.

Exchange—The rate of Exchange continues at par on all points north and east of us. Central money 23 ℔ cent discount; Alabama 20 @ 25. No sales of other depreciated bills to report.

CURING SWEET POTATOES.

MR. EDITOR—In looking over the last Cultivator, I see something said about curing sweet potatoes, which should interest a Georgian as much as does the Irish potato a Northerner, for I have long been of the opinion, that one acre of land well planted and cultivated in potatoes, would yield more profit to a family than any other cultivation we could give it, and, although it is generally admitted, it is frequently neglected, from the idea that they will not keep sound and good through the winter. This is all a notion, and, in too many instances, to be attributed to carelessness and a dependence on servants, who too frequently are reckless of the interest of their masters. I was brought up on a plantation, and of course partly raised on potatoes; for my father was always successful in raising and saving them, and his manner of planting and cultivating was something similar to Mr. McKinley's, for I do not recollect of ever seeing a potato hill on his plantation. I now have the same in possession, and have endeavored to pursue the same course of making and curing, and up to this moment have had no reason to complain of rotten potatoes at any season of the year.

My mode of putting them up is simply this: I dig so soon as I find the vines have been killed or bitten by the frost, (cotton or no cotton in the field.) I then select my seed from the eating roots, being careful to have no cut or broken ones thrown with them. I then have them carried and put in a potato house, built expressly for the purpose. It is built of small logs, and left rather open except at the end where I pack up the potatoes. The house is long and narrow, and should be built according to the quantity a person is in the habit of making. Before digging, I am particular in having the house perfectly dry, and a plenty of dry sand to cover the potatoes with. The ground is scraped off until it is hard and smooth. I then have the potatoes deposited, and as they continue to rise on the sides of the house, I place, with a shovel, the dry sand a few inches thick between the wall and potatoes, which is two sides and one end.—I then leave them in this situation until I find a change in the weather, which gives them a chance for airing and drying. If a few sharp frosts should come along, I throw a little light straw or grass over them, and remove it when the weather becomes more warm; but so soon as I find it getting cold enough for freezing, I then throw my dry sand over the naked potatoes until they are completely covered; and in this and no other way have I saved them until late in the spring.

It may appear to some that this preparation will be rather troublesome; but they should recollect, when it is once effected it is but little trouble, for the same house and sand will last a lifetime.

Should any doubt my plan and assertions, all I have to say is for them to try it, and should they have cause for talking of rotten potatoes, let them call on me the 24th of May, of each and every year, and they shall have a potato dinner.

A PLANTER.

Green County, Ga., May 10, 1843.

EDEN, EFFINGHAM COUNTY, GA., May 16th, 1843.

MR. EDITOR—In your last number you invite communications upon the subject of preserving the sweet potato. As I have had some experience in that way, I will give you what I have found to be the most successful plan. Large hills or banks never keep so well as small ones; twenty bushels are sufficient. I open a hole or bed about a foot deep, in high dry land, (deeper would be better,) put the potatoes in in a conical form, and cover with pine straw and corn stalks, or stalks alone, at first, and then with earth from eight to twelve inches deep. Covering lightly at first and increasing the quantity of earth as the cold increases, would probably be better; but I have always found more risk in covering too lightly than too heavily. The only advantage in putting straw or stalks, is to keep the earth from mixing with the potatoes, as I have no doubt they would keep equally well, or better, to put the earth on without either straw or stalks. I built a house some years ago of clay, the walls about a foot thick, and covered (under the roof) in the same manner, but I found it would not preserve my potatoes. When I open a hill I now remove the contents to this house during winter, but in spring, say early in May, I remove my potatoes to a dry house or loft, for if left in the hill, they sprout or become too moist and soft to be good. I seldom keep the Spanish so late, but I rarely fail to have the yam till new potatoes are dug.

I have no doubt Mr. McKinley's plan for planting is good in the up country, or where the land is stiff and dry, but in our level, sandy soil, I think the bed much better. He thinks it best to air or dry the potatoes before they are put in the hill. This I consider decidedly injurious, and inconsistent with his next plan, of putting them under the ground, which, he says truly, is the natural way. I believe the sooner the potatoes are put in the hill after they are dug the better.

While upon the subject of the potato, allow me to enquire, through your valuable paper, whether any experiments have ever been made to test the practicability of making sugar from sweet potatoes, as I have no doubt the yam potato is equal, if not superior, to the beet for that purpose.

Very respectfully yours,

C. POWERS.

MODE OF STOPPING GULLIES IN LAND.

MR. JONES—It is a matter of no small magnitude to know effectually the best plan to stop washes through our fields. In consequence of so many small valleys or washes on our hill sides, many of our planters are prevented from manuring, from the fact that the manure will all wash away in a short time, and those valleys are also a preventive of horizontal ditching, as the water will still be conveyed in them, consequently they cannot be ploughed across after running the side ditches. To remedy the evil I will here give my mode of effecting this desirable object.

Before I commence running my ditches, I haul leaves from the woods and cover over the galded places to a depth not to be difficult to plough. I then commence with a dagern plow in the bottom of the gully, plowing up and down the whole length of the valley or gully, throwing the dirt in the valley from both sides, until I reach the level part of ground; then if the first operation does not fill up, I repeat it until the valley becomes a plain. After this is done you can run your side ditches, and manure to your liking, and it will be as easy to cultivate as any other part of the field.

But some will say that "my gullies are too deep," (true enough) and how to prevent its progress they are at a loss to know. To such unfortunate farmers I would say, gather every combustible that can be procured, and fill up the deep gullies* to within one foot of the top, take your dagern plow and commence in the edges of the gully, and with hoes haul the dirt over this filling, and in the course of two years you can make this a plain and cultivate over it. The filling may be any thing you can procure, such as rocks, logs, brush and other things, no matter what so the gully is filled. If rock is used it should always be put at the bottom. I have often been defeated in stopping gullies by throwing in logs, making dams across, which always made two for one.

This work should be done in the winter, when

the ground is soft, and the side ditch run without delay, to prevent a loss of labor.

If this mode of improving our land is taken in time, it will prevent much labor; for so long as hilly land is cultivated without side ditching, so long will it continue to wash in gullies, and become more difficult to stop. Had our farmers commenced this mode of improvement years past, our old red hill Georgia would now present quite a different aspect; but* alas! alas! it is not so.

Mr. Editor, I long to see the day when the Cultivator will be filled with the productions of Georgia writers; then I shall know that improvement is with our farmers; but so long as we neglect to exchange ideas, so long will we continue to follow our old plans of culture, and the consequence will be light crops and a yearly increase of gullies. Say who will try the experiment. Come, let me hear from you.

JOHN ROOT.

Green County, Ga., May 11th, 1843.

*Some gullies are too deep to do any thing with.

To the Editors of the Southern Cultivator:

GENTLEMEN:—I am much pleased to learn that you are publishing a paper devoted to agriculture in Georgia. I have not seen your paper, and, therefore, can say nothing of its merits; but surely something of the kind is much needed among us. We murder up land and timber in Georgia, as if we all believed in Millerism. The object of the machinist is, with a given power to overcome the greatest resistance, or to produce the greatest possible effect. So the object of the planter should be, with a given amount of capital and labor, to produce the greatest possible amount of wealth, and to do this he must get all the information he can on the subject. The wealth and prosperity of our country depends on the industry and economy of the people. But surely it is possible to be industrious to little purpose, or to work to disadvantage, and this thing does actually happen among us. To cure, or at least qualify, this evil, is what I suppose to be the object of your paper, and that it may be well conducted and well patronised, I think must be the wish of every friend to the country. I only plant on a small scale, and I am reading two papers of the kind already, so that I can not say whether I will take your paper the present year or not; but I wish to see it very much, and perhaps you would do well to send me one number. Should I conclude to take it, I will send you the change immediately; if not, I will at all events show it to such of my neighbors as I think will take it.

The silk culture is now getting some part of the attention in the United States which its vast importance to the country requires, and, because of this, I will take the liberty to make some remarks on that subject, which you can dispose of as you like.

I have been cultivating silk, in a small way, for several years, and my experiments prove, I think, conclusively, that it is an easy matter to produce silk in Georgia. My constant success in the business will not admit of any other conclusion. I know but little about the business, and when I commenced I certainly knew less, and yet I have been constantly successful. We have surmounted what are known to be the greatest difficulties in the business, and so have others, and so may all that will. I have read some on the subject, and have thought much, and, after all, I firmly believe that silk can be cultivated in Georgia to as much profit as it can be in any part of the world. From every thing I know on the subject, the time, I think, will come, when it will be ascertained that Georgia silk is a superior article.

It is, I think, admitted by every person who has used our sewing silk, that it is from 10 to 25 per cent stronger than Italian silk, and if we had the same skill in manufacturing the article that they have in Italy, our silk would surpass theirs as much in beauty as it now surpasses it in strength. I believe, and believe candidly, that the silk culture can be made a better business in Georgia than cotton ever has been.—Whether I am mistaken in this matter or not, I certainly believe it, and I should not be acting the patriot to keep silent on the subject. I believe every body in this neighborhood admits now that silk is easily produced, and surely every body knows that it is a valuable article when produced, and, notwithstanding all this, little interest is taken in the matter. What I think is wanting in this section is, a market for cocoons and raw silk. If there was a market for cocoons, the very poorest people could and would make them, for it neither requires much capital or skill to do this much. A black man of mine one year made three bushels of splendid cocoons in his own time. These were worth $12, and this was about as much as he could have made at any other business, provided he had devoted his whole time to it. I am pretty sure that if we knew as well how to cultivate silk as we do cotton, we could make it for $1½ per pound. The writers on the silk culture have had too much to say about flues, furnaces, stoves, thermometers, &c. &c. In this way they have magnified the difficulties and thus discouraged the people. I cannot say but all these appendages may be necessary in other places, but, to my certain knowledge, here they can be dispensed with. There is certainly but little difficulty in any part of the business in Georgia. The reeling is given up to be the most difficult operation, and this I think less difficult than the art of spinning cotton. The difficulty in reeling silk lies entirely in the value of the article. If silk was worth no more than cotton, we should have plenty of silk reelers. Every person that commences reeling silk is certain to spoil some of it, and spoiling or wasting so valuable an article is surely not a cash business, and here they abandon the reeling.

Since I commenced writing this letter, a lady who has been in the business and abandoned it, tells me she would commence again if she could get $2 a bushel for cocoons. Now the value of cocoons is from $3 to $5 a bushel. Another lady told me she thought her silk did not cost her more than wool. I have had more experience in the business perhaps than any person within fifty miles of me, and my opinion is that cocoons can be produced at $1. I would rather make cocoons than wheat at the same price.

It is a mistake to suppose the prosperity of this country depends on any thing but the industry, skill and economy of the people. If a great many people are idle in the country, poverty will be the consequence, whether they are idle from necessity or choice, the result will be the same. A great many people in our country are, no doubt, idle from choice, but there are some idle "because no man hath hired them." Humanity, justice and the good of the country, all require that these should have employment, and that the silk culture can be made to give a profitable employment to an immense number of persons, is a matter about which I have not the shadow of a doubt. The condition of our country, beyond all doubt, requires the best exertion of all its friends. In every direction we see nothing but distress and privation; and, if we may believe our newspapers, or our eyes, the moral condition of the country is no better than that of its pecuniary condition. All these evils originate from the same prolific source.—Idleness, beyond doubt, is one of the greatest sources of moral and physical evil known in our world, and yet it goes unrebuked. Every idle person is as certainly maintained by those that are not idle, as a man in jail is maintained in that way, and unless a person contributes to the good of the country in some way, he is just as certainly an evil, as a great fire in a city is evil. In Georgia we are cursed with blessings. We have a climate that produces almost every thing that is produced in the world. We have iron mines, gold mines, water power to a great extent, and we can produce silk, one of the most valuable articles in the world, in away that I certainly do not believe it can be produced elsewhere, and yet, under all these circumstances, we are not ashamed to cry hard times, hard times.

I have carried on the silk in connection with other business, so that it is impossible that I could give details, and, besides that, I have not paid that attention to facts that I might have done. I never measured or weighed my cocoons but one year; that year I made in out buildings and a part of our dwelling, 44 bushels. I am sure a person can reel a pound of silk in a day, and can wind it in less time. The worst operation is to twist it. A young lady in our employ has twisted, on a common cotton wheel, one-third of a pound of sewing silk in a day, and, in another day, the same young lady twisted 28 cuts of warp, or warp for 2 8-10 yards.

Yours, respectfully,

A. E. ERNEST.

Bibb County, May 11th, 1843.

TO CURE BUTTER.—Take two parts of the best common salt, one part of sugar, and one part of saltpetre; beat them up, and blend the whole together. Take one ounce of this composition for every sixteen ounces of butter, work it well into the mass, and close it up for use. Butter cured in this way, appears of a rich, marrowy consistence and fine color, and acquires a brittle hardness nor tastes of salt. It will likewise taste good three years, only observing that it must stand three weeks or a month before it is used.—*Selected.*

MR. FOOTE'S PRIZE ESSAY.

[Concluded from page 75.]

MARL.

Marl being but a modification of lime, combined with variable proportions of divers other substances, it may be observed, in general, that whatever principles are applicable to lime, (after having been deprived of its causticity,) are applicable also to the use of marl, so far as its *nature* only is regarded. We shall, therefore, treat but very briefly of this substance. Suffice it to say, that its value has been highly appreciated in Europe, and in those portions of our own country where it has been most extensively employed, and that, wherever it is practicable, the strong probability is that the farmer will find his interest in making a thorough trial of it.

The most common locality of marl is low, wet swamps. It is readily distinguished from other light soils by its light grey color when wet, and its white, chalky appearance when dry.—Its whiteness, indeed, will commonly indicate pretty nearly its comparative value; since both depend on the amount of lime it contains. A sure test, however, of the amount of lime present, will be to apply to it a few drops of sharp vinegar. If the marl be worth employing as a manure, it will effervesce; i. e. small bubbles will appear, occasioned by the escape of gas.

In applying marl to different kinds of soil, particular reference should be had to two circumstances; 1st. The amount of its calcareous matter. 2d. Its texture. If the proportion of its calcareous matter be large, the smaller will be the quantity proper to be applied, and vice versa. Again, if the marl be of a strong adhesive texture, containing a large amount of clay, its application will be most profitable on loose, silicious soils; if on the other hand, it be of a sandy or shelly character, strong loams and clays will be most benefitted by its reception.—The common mode of its application is to spread it evenly over the surface, and in case of cultivated crops never to turn it under till it has been thoroughly crumbled down by the action of the atmosphere. The reason of this practice is thus stated by Chaptal: "It is necessary for earths, in order to possess great fertilizing powers, to be saturated with all the principles which they can imbibe from the atmosphere. Thus those which, by the depth of their beds, have been constantly secluded from the action of the air, will require to be exposed to it a longer time before becoming fertile. The lime contained in marl, as it is taken from the bed, is never saturated with carbonic acid; but after being exposed to the air, it becomes at length saturated with the acid it receives from it, crumbles and effervesces. The decomposition of marl may be hastened by frequently turning it, so as to allow the air free access to the lime; and this method is generally practiced by those who employ marl as a manure."—p. 44.

The quantity applied per acre may vary, according to circumstances, from five to twenty-five or thirty wagon loads. For a full discussion of this subject, see Hitchcock's Geology of Massachusetts, a copy of which has been lodged with the town clerk of every town in the Commonwealth.

GYPSUM, OR PLASTER.

Plaster, first introduced into the United States from Paris by Dr. Franklin, has effected the most important improvement in agriculture perhaps that has ever been made. Extensive districts in this and other countries, have been benefitted by its introduction to an extent which, considering the comparatively *small amount* of the substance employed is truly astonishing. In Germany, says Lampodius, one of her own agricultural writers, "It may with certainty be stated, that by the use of gypsum, the produce of clover, and the consequent amount of live stock have been increased *at least one third*."

"There are, however, some tracts of country where the use of plaster has been attempted without success. But this arose from its being one of the original constituents of the soil, which derived no advantage from the addition of a new quantity. The existence of this salt naturally, in those lands upon which plaster produced little or no effect, has been proved by analysis."—Chaptal, p. 73.

Much mystery has heretofore enveloped the modus operandi of this manure; but before the light of science the cloud is vanishing away.—Many have supposed its efficacy to arise from the *specific food* which it furnished to certain plants, as to clover, for instance, which seems especially benefitted by its application. But when we consider that by the application of a *handful*, as it were, of this manure, upon an acre of good ground, the product is increased from a few hundreds to *tons* of grass, it is at once apparent that, on such a supposition, the cause is wholly inadequate to the effect. It was reserved for the gifted and honored Liebig to lift the veil, and to produce a theory, not only plausible in itself, but fully sustained in all its parts by the experience of practical men.

His theory is this: that the efficacy of plaster consists in its arresting, as it rises in exhalations from the soil, or descends in rain, dew or snow from the atmosphere, the ammonia which is generated by the decay of animal matter and appropriating it to the use of the growing crop. We will permit him to present his own views, however, in a few extracts from his Organic Chemistry.

"Nitrogen exists in every part of the vegetable structure."—p. 88. "All animal," [and vegetable] "bodies, during their decay, yield the nitrogen which they contain, to the atmosphere, in the form of ammonia."—p. 72. "The evident influence of gypsum depends only upon its fixing in the soil the ammonia of the atmosphere, which would otherwise be volatilized, with the water which evaporates."—p. 75. "In order to form a conception of the effect of gypsum, it may be sufficient to remark, that 100 lbs. of burned gypsum fixes as much ammonia in the soil as 6250 lbs. of horse's urine would yield to it."—p. 88. "If a field be strewed with gypsum, and then with putrified urine, or the draining of dung hills, all the carbonic of ammonia will be converted into the sulphate, which will remain in the soil."—p. 184. "If we strew the floors of our stables, from time to time, with common gypsum, they will lose all their offensive smell, and none of the ammonia which forms can be lost, but will be retained in a condition serviceable as a manure."—p. 185. "But this is not all. When we give a plant nitrogen in considerable quantity, we enable it to attract with greater energy from the atmosphere, the carbon which is necessary for its nutrition."—138. Now "carbon enters into the composition of all plants."—3. So that, by strewing a field with gypsum, we enable plants to supply themselves from the atmosphere, not only with nitrogen, on which their most nutritious principles depend, but also with carbon, the chief constituent of all their frame work.

This theory is confirmed by several circumstances which have long attracted the attention of the observing farmer.

1. It has been observed that plaster acts with increased efficacy when applied in connection with manures, or recently manured lands. The solution of the phenomena by our theory is easy and satisfactory. The ammonia, which would otherwise escape from the decomposing manure into the atmosphere, is seized upon by the plaster, detained in the soil, and wholly converted to the use of the growing crop.

2. It has been observed that plaster acts with greater power on soils which have been recently stirred, than on those which have lain for a long time unmoved. Solution—By stirring the soil its porosity is increased; consequently it absorbs more freely the dews that fall upon it—from which the plaster separates and hoards up in the soil, the rich deposits of the atmosphere. In proof of the extent to which the atmosphere is charged with fertilizing matters, which the rains and dews are constantly depositing upon the surface of the earth, we will here introduce the substance of a statement made to the American editor of Liebig, by Mr. E. Tufts, of Charlestown.

"Eight years since, about three quarters of an acre of land, situated on one side of a lane and on a declivity, were broken up. About the same time, the propriotor of a field on the opposite side of the lane, and above the land of Mr. T., commenced gardening on a large scale, and formed an immense bed of compost in the lane. This heap was made up of animal and vegetable matters, and from receiving constant additions is continually undergoing fermentation, and the gases and vapors emanating from it are always perceptible. Four years ago Mr. T. observed, that in some inexplicable way, his land had become so fertile as to induce him to dispense with the use of manure; he has not since used it, and is now fully persuaded that its fertility is owing to certain vapors arising from the heap and then descending on his land. None of the soluble matters of the heap are carried to Mr. T.'s field, no manure has been applied, and its fertility continues unimpaired."—*Appendix to Liebig, p.* 366.

3. Plaster has been observed to produce but slight effects upon old, dry and hide-bound meadows. Says Liebig, (p. 87,) "Water is absolutely necessary to effect the decomposition of gypsum, and also to assist in the absorption of the sulphate of ammonia by the plants: hence it happens that gypsum is not observable on dry fields and meadows." To which may be added, that but a small quantity of putrescent matter existing in such cases, the exhalations are inconsiderable; and what is deposited from the atmosphere by dews cannot be absorbed by the soil in consequence of its compact, impenetrable surface. On old, and even dry pasture lands, the effect is much greater, there being ever present on their surface, a portion of manure to serve as a basis for its action.

4. It has been universally observed that the most striking effect of plaster is on the clover crop. Reason—"Red clover contains double the quantity of nitrogen that common hay does."—*Gray, p.* 158.

5. It has occurred, in the experience of different farmers, that where one part of the field is sown with plaster immediately before a thunder shower, and another directly after the same shower, the portion sown first was benefited in a far higher degree than the other. Reason—"Rain water must, at all times, contain ammonia, though not always in equal quantity. It must be greater in summer than in spring or winter, because the intervals of time between the showers are greater. The rain of a thunder shower after a long protracted drought contains the greatest quantity which is conveyed to the earth at any one time."—*Liebig, p.* 73.

6. Considering the beneficial effects of plaster at large, it has been observed that they depend, in general, not so much on any peculiarity in the location, or composition of soils, as on those physical conditions which render the surface of the soil an easy medium for the transition of soluble matter: all of which must go to corroborate the theory in question.

From the views thus presented, we are led to infer—

1. That the atmosphere is an inexhaustible source of food for plants. 2. That the most available agent for securing the benefit of this food to plants is plaster. 3. That viewed in this light, the value of plaster in agriculture can hardly be over-rated. 4. Then it may be safely recommended for general use on all soils containing a portion of fermentative matters, and not so compact or wet, as to prevent the process of exhalation and absorption. 5. That it should always be applied to the surface of the soil, or at least within the influence of the atmosphere. 6. That it should be sown at an early date in the season, before the period of the most abundant dews and exhalations has commenced. 7. That it should always accompany manures used as a top dressing, or only slightly buried in the soil: and 8. That it should be liberally

employed about our barnyards, stables, vaults, manure heaps, compost beds, &c.—not however in compost under the supposition that it will hasten the fermentation of the mass. "Davey has refuted this opinion by direct experiment, placing it beyond a doubt, that the mixture of plaster with manures, whether animal or vegetable, does not facilitate decomposition.—*Chaptal, p.* 74.

The proper quantity to be used when sown broadcast upon the field, has been decided by experience, as also by chemical science, to be from one to one and a half bushels per acre.

WOOD ASHES.

Ashes, whether "live" or leached, considering the certainty, uniformity and power with which they act, as well as the permanency of their action upon vegetation, may well be ranked among the very best manures. The *fact* of this superiority over other manures is very generally understood: the *reason* of this superiority appears quite obvious when we reflect that they are composed entirely of organised matter, reduced to the most consolidated form, and when, further, we learn from chemistry that their chief bulk consists of the very material which enters most largely into the finer grains and grasses. Yet, strange as it may be, no inconsiderable portion of this priceless article is suffered to be lost to all the purposes of cultivation, being permitted to lie waste about our dwellings, and to disappear as useless rubbish. To this remark, however, we find (by going to be sure a great way off for it,) one very striking exception.—Even leached ashes, transported thither from every State in New England, and all the way from the Canadas, "are bought up on L. Island at an expense of from 35 to 50 cents a bushel, and considered a profitable investment at that."—*Cult. vol.* 6, *p.* 42.

The most profitable use of this manure, when applied directly to crops, is probably on light silicious soils—ashes being admirably calculated not only to improve the texture of such soils, but to furnish to them just that kind of organic matter in which they are most liable to be deficient. They may be applied, however, with certain benefit to any soil, and that either by spreading them upon the surface of grass or grain lands, or by applying them to the hill or drills in the case of hoed crops. The practice of dropping a handful in the hill at the time of planting, has been practised by many farmers, and with excellent results. But perhaps their highest value will be found in the compost bed, since being capable of liberating a large amount of nitrogen, they will greatly promote the process of fermentation. "One bushel of ashes contains 5½ lbs. of potash, a quantity sufficient to decompose 200 lbs. of peat earth."—*Gray's Elements, p.* 318.

SALTPETRE.

Saltpetre, as a manure, has been employed in the way of experiment, by several of our enterprising farmers, and in some instances with signal benefit to the crops to which it has been applied; its use however has been abandoned by the most judicious, as being more expensive than profitable. That a solution of this may be serviceable for soaking seed corn, has been established by the experience of many of our farmers. That it may also be employed effectually, to banish the canker-worm from our apple orchards, appears from an experiment made by O. M. Whipple, Esq. of Lowel—an account of which may be found in Colman's Fourth Report, p. 335.

Considerable quantities of this subject frequently accumulate in combination with earth, under old buildings, particularly barns and horse sheds—when available in this form, the expense of saving and applying it will always be exceeded by the profit.

COMMON SALT.

Common salt, highly recommended as a manure by some, has been as much depreciated by others, and hence, when directly applied, is considered as a doubtful fertilizer by almost all.—The obscurity in regard to its use, however, rests chiefly on the quantity which ought to be employed. The result of comparative experiments made in Germany, showed that a very few pounds per acre were sufficient to produce a largely increased return of grass—while in England it has been beneficially applied within the wide limits of from 5 to 20 bushels per acre, and when used for cleaning the land in autumn, of 30 bushels an acre.—*Appendix to Johnson, p.* 5.

Employed in moderate quantities in composts, salt is highly promotive of fermentation; applied liberally late in the fall, or early in the spring, is very destructive to worms and insects; used in the form of a brine for soaking seed wheat, it prevents the smut; and it otherwise acts beneficially—by stimulating the absorbent vessels of plants, or imparting to them direct food: by preventing injury from the sudden transitions of temperature, and by increasing the moisture of dry hot soils. It has a specific effect upon all plants of the cabbage and onion tribe—nothing is more beneficial to an asparagus bed; and it is suggested to those who consult their own interests by rearing the most valuable kinds of fruits, to try the experiment, cautiously, of applying salt or brine in moderate quantities, about the roots of their trees.—*Farm. Cabinet.*

Whether, however, it will be expedient for farmers to introduce this manure in general practice, even if it suit his particular soil, is wholly to be decided by a reference to its comparative expensiveness.

CHARCOAL.

"Charcoal," says Liebig, "surpasses all other substances in the power which it possesses of condensing ammonia within its pores, particularly when it has been previously heated to redness. It absorbs 90 times its volume of ammonial gas, which may be again separated by simply moistening it with water."—p. 89.

"It is by virtue of this power that the roots of plants are supplied in charcoal exactly as in humans, with an atmosphere of carbonic acid and air, which is renewed as quickly as it is abstracted."—p. 91. Being at the same time "the most unchangeable substance," it is not surprising that it should constitute, not only one of the most powerful, but quite the most *durable* manure in existence.

In the language of J. Hepburn, Esq., of Lycoming, Pa., (Cult. vol. 9, p. 106.) As charcoal is almost indestructible, and its effects remain as long as it exists in the soil, it is possible that it may be found one of the cheapest as well as most efficient manures for some crops and on some soils. It appears evident from the manner of its action, that plants requiring the greatest supply of nitrogen would be the most benefited by its application, and hence its efficacy when given to wheat."

Again, "charcoal has a *physical* as well as a chemical effect on soils, decidedly useful. It renders them as far as it is present, light and friable; and gives additional warmth to them by its color, which absorbs and retains readily the rays of the sun during the day." Mr. Hepburn also states the important fact, that whenever charcoal has been applied *rust never effects the growing crop of wheat.*" Its use may also be recommended, on trustworthy authorities, as an excellent means of curing diseased trees and unhealthy plants. In the neighborhood of forges, furnaces, smithies and coalpits, considerable quantities of this manure can be obtained at trifling cost, and it becomes the vigilant farmer to see that none of it is suffered to be lost.

SOOT.

This substance, consisting chiefly of geine, nitrogen, and the salts of lime, potash, soda, ammonia, is ranked by Dr. Dana "among the most powerful of manures in the class consisting of geine and salts. He observes: "On the principles adopted for determining the value of manures, the salts in 100 lbs. of soot, are equal to one ton of cow-dung. Its nitrogen gives in a value, composed with cow dung, as 40 to 1."—*Manual, p.* 161.

A most satisfactory experiment with this substance has been tried by the writer the present year. From two to three quarts of soot, which had been collected from the fire place the last autumn, and lain exposed to the weather thro' the winter, was, some time in April, carefully incorporated with the soil about the roots of an egg plumb tree, which though it had borne fruit repeatedly, had attained but a very small size, and had not in the last seven years put out so many inches of new wood. The result has been, that, by actual measurement, it has sent forth numerous shoots the past season, from two to three feet long, and one to the length of four feet and a half.

SAND, GRAVEL AND CLAY.

Pure sand and gravel, from the obvious tendency they have to separate the particles, and thus increase the porosity of a tenacious and compact soil, may readily be supposed to possess no inconsiderable influence in improving such lands, as by retaining too much water on their surface, are rendered unpleasant and difficult of cultivation and to a greater or less degree unfruitful. It might also be taken for granted that pure clay would be alike beneficial when employed to give solidity to such light and porous soils as are incapable of retaining manures, and exposed to suffer severely from drought.

"On sandy soils, a load of clay properly incorporated, will produce a greater, because a more lasting, effect, than a load of manure. Of this the fine farm formerly owned by Judge Buel, is an example. This was originally a hungry, porous sand. To give it tenacity and proper retentiveness of moisture, Judge Buel covered his fields with clay from the Albany claybanks, at the rate of from 20 to 30 loads per acre; and his experience convinced him that a load of such clay (it contained from 20 to 30 per cent of lime,) was of more benefit than a load of barnyard manure. He distributed his clay as fast as drawn, upon the sward or surface, where it was decomposed by the rains and frosts, when it was pulverised by the roller, and further distributed by the harrow.—*Cultivator, vol.* 9, *p.* 45.

"Even sand upon clay, or clay upon sand, are beneficial applications to improve the soil: the only question being, how far the benefits will repay the expense of application. The earthy materials are to plants, what the stomach is to animals—the recipient of food, and the labratory of the main process of nutrition. The presence of clay lime and sand, are all essential in the soil, to enable it to perform its healthful functions. Where either of these is naturally deficient, it may be artificially supplied with manifest advantage."—*Cult.*

COMPOSTS.

The *absolute value* of a compost depends on the amount of food it is capable of furnishing to plants. Its value *in relation to a particular soil*, will depend also, in a measure, on the effect it is calculated to have on the *texture* of the soil. The question of profit in *making* composts at all, depends upon whether, by any means, the farmer can incorporate with his soil any valuable animal, vegetable or mineral substances, which he might not *otherwise* appropriate to his crops with equal benefit, and at an equal expense.

One thing is certain; "nothing can be *added* to the elements of fertility by mixing animal, vegetable or mineral matters in a compost heap." The only questions then to be decided are, 1. Can any fertilizing matters within the farmer's reach be *better saved*—i. e. *more profitably* saved by the employment of compost heaps; and 2. Can any such matters be more cheaply brought into *a fitter state for the use of plants*, by their means. The first of these questions, it is believed, will not, as a general thing, admit of an affirmative answer;—for, by following the directions already laid down for the preservation of manures, the object will be nearly if not quite as effectual, and far more cheaply accomplished than by resorting to composts.

The only consideration then, if "we have thus far trod on solid ground," which can render the system of composting highly advantageous to the farmer, will be the circumstance of his having on hand such animal or vegetable matters as cannot properly, or to a sufficient amount, be decomposed in his barnyard. Such exigency will not be unfrequent. The farmer may have the misforture, by accident or disease, to loose a horse, a cow, or a score of sheep.—These are all appropriate subjects of the compost bed, and should never be suffered to decompose in the open air, so long as earth of any kind can be obtained to cover them, and to absorb the nitrogen which will escape during the process of putrefaction. Again, peat earth, swamp-muck, and similar substances, in which there exists a large amount of coarse woolly fibre, may be the most conveniently, and most effectually reduced to a proper condition for the use of plants, in compost beds—especially in case a large amount of these matters is required in the operations of the farm.

How, then, the question now arises, shall we most readily, and at the least expense, effect the decomposition of these matters? or, in other words, how shall we convert their insoluble into soluble genie—the direct food of plants.

"Every azotized constituent of animal or vegetable organism enters spontaneously into putrefaction, when exposed to moisture and a high temperature. Accordingly, azotized matters, (i. e. matters containing nitrogen in any of its forms,) "are the only causes of fermentation and putrefaction in vegetable substances.—(Liebig, p. 230.) "It is a well established fact that the production of nitre is not necessarily dependent on the presence of animal matter, but that, under the influence of porous materials, aided by alkalies or lime, the elements of air combine and form nitre and nitrates."—(Dana, p. 135.) From all which it appears necessary for the decomposition of vegetable fibre, viz: 1. A sufficient degree of moisture; 2. A proper elevation of temperature; and 3. The presence of some substance containing nitrogen—which may be either pure animal matter, animal manure, lime, (the principal alkaline earth,) ammonia, potash or soda, (the most important alkalies,) saltpetre, (nitre of potash,) ashes, (consisting of potash, soda and lime, common salt,) chloride of sodium.

The efficiency of these substances as decomposers, will probably be found to correspond somewhat with the order in which they stand; but in making from them a selection for his particular purpose, the farmer must of course be guided by circumstances. Whether his interests will be subserved at all by making compost, will depend upon his facilities for accumulating undecomposed vegetable matter. Whether it will quit cost to employ his stable manures in composts, will depend upon the extent to which he can secure them (solid and liquid,) in his cattle yard, or in his soil; and upon the cheapness with which he can procure other decomposers; and whether he shall make use of lime, or any one of the alkalies, or alkaline compounds, in preference to another, he will decide with reference to the comparative expense of these articles, and the idea he has of their comparative value.

If animal manure be decided upon as the decomposer, it should be employed in as green a state as possible, its decomposing power depending entirely on its nitrogen, which even an incipient fermentation will diminish. The proportion in which the manure is to enter into the compost should be determined by the species of the manure—it being recollected that urine, night-soil, hog dung, sheep dung, horse dung and cow dung, contain different amounts of the decomposing principle (nitrogen,) corresponding with the order in which they are here arranged. The common practice has been to allow one load of manure for two or three of vegetable matter; but it has been shown that this must depend on the quality of the manure.

It is equally evident that the proportion of vegetable matter should be regulated by the ease or difficulty with which it is likely to be decomposed, or, in other words, by the amount of labor it will require the manure to perform. If the vegetable matter to be decomposed be peat earth, or swamp muck, it should have a previous opportunity of parting with its tannin, acids, and excessive moisture, by exposure, for some length of time to the atmosphere.

The ingredients being in the requisite state, and the proportions of their admixture determined on, the pile may be constructed as follows: First, lay the foundation (of the form, size and depth desired,) with vegetable matter—cover this to the proper thickness with the manure, and thus proceed with alternate layers of vegetable matter and manure, till the pile has acquired a sufficient height, when it should be finished (in a somewhat conical form,) with a *thick* layer of earth, to prevent the escape of such volatile products as will be formed during the subsequent fermentation. If it be wished to hasten the process, lime, ashes or salt may be added for this purpose; and, in any case, a small addition of plaster will be useful, from its tendency to preserve the salts of the pile.

At the end of six or eight weeks the whole mass should be shoveled over, broken down and carefully blended together, and in case fermentation is still proceeding, a quantity of the finer earthy materials may be added. As soon as the work of decomposition is done, it should be removed immediately to the place of its destination.

"Weeds, leaves of trees, and all the succulent plants which grow so abundantly in ditches and waste lands, under hedges, and by road-sides, if cut or pulled when in flower, and slightly fermented, furnish from 20 to 25 times more manure than straw does. These plants carefully collected, furnish to the agriculturist an immense resourse for enriching his lands. The turf that borders fields and highways, may be made to answer the same purpose, by cutting it up with all the roots and the earth adhering to them, rotting the whole in a heap, and afterwards carrying the mass upon the fields."—*Chaptal, p.* 63.

To form a compost with lime, our late Agricultural Commissioner, (Rev. H. Colman,) directs to "raise a platform of earth on the headland of a field, eight feet wide, one foot high, and of any length according to the quantity wanted. On the first stratum of earth lay a thin stratum of lime fresh from the kiln; dissolve or slack this with salt brine from the nose of a watering pot; add immediately another layer of earth; then lime and brine as before, carrying it to any convenient height. In a week it should be turned over, carefully broken and mixed, so that the mass may be thoroughly incorporated. This was applied in the hill to corn. The crop was equal to that obtained by barn manure on parts of the field immediately contiguous."—*Fourth Report, p.* 347.

In forming a compost of peat and lime, Dr. Dana recommends to slack a cask of lime with so much brine as will just be saturated with a bushel of salt, and after 19 days blend it thoroughly with three cords of peat, shovel it over occasionally for six weeks, and apply it directly to the soil.—p. 197.

Of the use of clear brine in forming compost, there seems to be, among our most intelligent farmers, a considerable shyness. The result of Mr. Colman's observation on this subject was, that "in its application to peat composts, it assists in their decomposition, but its tendency is to expel their ammonia, to drive off the enriching parts ef the manure, and to reduce much of the remainder to an insoluble state. Here, however, its pernicious effects may be counteracted," (in para?) "where there is a sufficient covering of mould to absorb the gases, which would otherwise be dissipated in the air. Under such circumstances, its use may sometimes be advised."—*Fourth Report, p.* 349.

Mr. Timothy Benedict, of Pittsfield, in the fall of 1841, prepared a compost heap of swamp muck and lime, by mixing one bushel of the latter with a common load of the former, taken fresh from the bed. The last spring he applied this to a portion of his cornfield, a shovel full to the hill, treating the remainder of the field in similar way with common stable manure.—When examined by the Agricultural Committee in September, it appeared that the compost bed had been equally efficacious as the manure. The crop was a luxuriant one, and received the second premium of the Society.

The writer's experiments with muck and lime, however, both on gravelly and clayey soils, have proved entirely unsatisfactory; while from the use of the same quantity of muck in combination with ashes, he has derived the most signal benefit.

Ashes and muck, in the proportion of 4 or 5 bushels of the former to a common load of the latter, form a very valuable compost. If the muck be in a fine powdered state, the materials may be thoroughly blended together, and applied at once to the soil. But if the muck be of a strong texture, and contain much vegetable fibre, some time will be necessary for its decomposition. Leached ashes will answer the purpose equally as well as lime, if a somewhat larger proportion be employed.

To this compost too high a valuation can hardly be attached. A series of experiments (amounting to 29 in number,) instituted the past season, by the editor of the New England Farmer, has resulted in showing it to be second in the scale of composts, only to one "composted of both the dung and urine of cattle, horses, hogs and human beings, mixed with straw and muck," in a barn cellar.—See the Farmer, vol. 21, p. 157.

Finally, it may be remarked in relation to compost heaps, that the more heterogeneous their materials, the more rapid and perfect will be their decomposition; since, the greater the number of affinities brought into play, the greater will be the struggle between the particles of the mass to indulge their "likings and antipathies" in making election of their future (though it may be very temporary) associates. Let not the manufacturer of composts, then, be afraid of laying under contribution too many of the sources of animal, vegetable and mineral substances capable of being made to fatten his plants and to "gladden the soil."

Occasion will be taken, in concluding, simply to express the sentiment, that would the present race of cultivators of the soil but "come to the light" which science is shedding upon their profession, and in accordance with its teachings, put in full requisition the resources of fertility which every where abound around them, another generation would inherit from their hands a land of garden spots, and "shout the merry harvest home," on fields where now is only heard the sad, monotonous complaint of "hard, hard times."

Ashes on Corn.—I have been in the habit of using ashes and plaster on corn, and believe that ashes are worth the most, I thought last spring that I would ascertain the fact. I therefore left six rows through the middle of my field No. 1 without plaster or ashes; six rows do. No. 2 with plaster in the hill on the corn; do. six rows No. 3 with ashes in the hill; six do. No. 4 with ashes and plaster in the hill; six do. No. 5 ashes and plaster in the hill, and on the corn after the first hoeing: the quantity used was about a table-spoonful to each hill. The rows were long enough to contain a quarter of an acre, each 6 rows. The result was—

No. 1 had	22	bushels ears.
2	24	"
3	26	"
4	26	"
5	31	"

The field marked out three feet each way, and the cultivator used each way, and hoed twice. Thus you see No. 1 would yield at the rate of 44 bushels per acre, No. 5 62 bushels per acre, which I should think about an average with the

rest of the field. The soil is a sandy loam, mixed with limestone gravel.

I do not wish to be understood that plaster is of no benefit to land, for I believe it is very beneficial; I believe if farmers would apply their ashes to their land, it would net them nearer 100 per cent. than 10 or 12.—*Cent. N. Y. Farmer.*

THE RUST.

The very general injury to the wheat crop last season by rust, appears to have given new impulse to inquiries after its cause, and to have enlisted in the laudable work of discovery, many practical and scientific farmers. We are gratified at this, as the interest involved is one of deep moment to the farming community, it being certain that unless the cause of the disease should be satisfactorily discovered, that its remedy must ever remain among the hidden mysteries of nature. One set of farmers believe in the theory, that the rust is occasioned by parasitical plants, which fix upon the stalks and eat up those juices which should go to the perfection of the grain—another believes that it is owing to *plethora* or *overfullness*, whereby more juices are generated by the root-feeders, than can be healthfully taken up by the plant, and converted into straw and grain, and hence a cracking of the straw, and, consequently a loss of those juices which tend to perfect both the straw and kernels of wheat.

Now those who ascribe the disease to parasitical or fungus influence, as well as those who refer it to plethora, agree in one thing, that this *disease* always occurs under a peculiar condition of the atmosphere, just before the time of ripening. This is admitted by both parties.—The one contends that the moist, foggy and sultry condition of the atmosphere, tends to encourage the settlement of parasites upon the stems of wheat, and their consequent taking root and growth, to the total abstraction of the pabulum of both stem and grain, and that this is the primary *cause* of the malady. The believers in the doctrine of plethora, view the presence of the parasitical or fungus tribe as the *effect* and *not the cause* of disease: that the exudation of fluid through the cracks, superinduced by a too exuberant flow of sap from the roots, attach the parasites to the stalks, where, in the glutinous pabulum which escapes from within and forms on the outerside, they not only find a safe lodgment, but food withal to sustain their growth—and that this state of over feeding is produced by the atmospheric cause to which we have alluded, it operating to bring about a superabundant supply of nutriment, thereby incapacitating the growing plants from healthfully digesting it, or of giving out aliment, in due proportion, to the organs requiring it.

The believers in the fungus doctrine, maintain that the seeds of this parasite take root on the straw and extract their sustenance from within, —while those of the plethoric faith, believe that before there is any lodgment of those parasitical enemies, the food is already prepared by the bursting of the stem and exudation of the sap, the which forming on the *outside*, supplies the enemy with the sustenance on which he is nurtured into disease.

We have thus stated the two theories, and would ask gentlemen who may engage in the laudable work of searching into the cause of this disease, to let their observations be thorough. The character of the soil, its situation and exposure, mode of preparation, kind of manure used, state of the weather, period when the rust may first make its appearance, its changes, the time it may take to perfect its evil work; whether the straw becomes cracked before the rust makes its appearance on the surface; if so, whether its color is light on its first appearance and becomes discolored subsequently to the straws being affected by the rust, and at what period the parasites are discernible. It would be well too, to mark those spots where the rust may *first* show itself, so as to ascertain whether the decomposition of the manure, if any may have been used, or clover, if a clover ley had been turned under, had been carried on to greater excess, than on those parts where the rust had not appeared so early. By carefully noting such phenomena, the observing farmer would be the better enabled to make up an intelligent opinion as to the true *cause* of the disease, than he could do, by quietly looking on and awaiting its fatal result. It is by watching the symptoms of human disease, in their every form, that the skilful physician is alone enabled to determine to what type to refer it, and by which he is enabled to point out and exhibit his counteracting remedies. Without this diagnostic supervision and philosophical inquiry, he would neither be able to determine the nature of the disease, nor make the appropriate use of remedial means—all his efforts would be failures; or at all events, should they prove successful, would be altogether accidental; for unless you first understand the nature of the disease, know what organs are impaired in action, and how impaired, it is groping in utter darkness to attempt their restoration to healthful volition.

Before the nature of the Typhus was understood, we have seen the patient relapse into syncope from the moment that the vein of the arm was opened, and the pulse sink under the loss of the most trifling quantity of blood, so that its motion became so thread like, as to be recognized with difficulty by the pressure of the most delicate finger—and we have seen the same patient, on the prompt tying up of the arm, and the administration of a potent stimulating drink, rouse into sensibility, and the pulsation so quickened in action, and filled in volume, as would, in any other disease, have justified the free use of the lancet—but in this, as the experience just related indicated, it would have proved fatal. Here the medical gentlemen found it imperiously necessary to observe the symptoms, study the nature, and contemplate the effects of the disease, and it was only after the most patient and searching investigation that they were enabled to adopt their sanative appliances; and we hold it, that it is equally necessary for farmers to bestir themselves in well directed observations, as to the nature of the rust —they must watch its appearance with eagerness, examine every phenomenon the disease may present, with coolness and discrimination, and by making proper deductions from the premises which may be presented, they may find out the *cause;* that once ascertained, and a remedy will be of easy discovery and application.—*American Farmer.*

SHEEP IN THE SOUTH.

Important Facts.—In Chester District, S. C., there is a gentleman who has been breeding sheep for 30 years. He was lately written to for information on the subject by one of our subscribers—and he replied at considerable length. This gentleman's experience sustains the opinion heretofore expressed by us, that this is the very country for sheep. An impression prevails quite generally among Mississippians, that sheep and wool will deteriorate in our climate; and this deters many from entering with spirit into sheep husbandry.

To correct this evil and erroneous impression, we mean to leave no effort untried. We therefore ask pardon for taking an extract from a *strictly private letter*, from the gentleman in South Carolina, above mentioned. He is a man, as we have said already, of 30 years experience in sheep-breeding—of fine education—and of extensive observation, having traveled in much of the best portions of Europe. He is, withal, a practical as well as a scientific farmer, attending, in person, to the operations on his own farm. His word, then, is *authority* on this subject, and he says:

"The *quality of wool will not deteriorate in the South;* and with proper care, can be preserved *as pure* in the South as in the North. I have some merino ewes and wethers, a cross of the Escurial and Guadaloupe breeds, *now giving* as fine wool as the original stock, after breeding them in and in, upon this farm, without any change for 30 years."

It is unnecessary to explain why no new cross or new rams were used, if it be remembered that Chester is about 200 miles from the seaboard, and that there is no fine stock in that region. As to the *quality of mutton*, every lover of that delicious meat knows well that the mutton of the south is unrivalled; yet on this point also, we shall draw upon the above mentioned letter.

"The opinion," says the writer, "as to the inferiority of merino mutton is mere prejudice.—After the experience of 30 years, I can say, from my own taste, and the praise of it at my table, that it is equal to any mutton in the world—Welsh mutton not excepted."

The writer knew what he was speaking about —for he had bred South Down, Bakewell and Tunis.

We earnestly entreat our farmers to bear these facts in mind, and to pay more attention to sheep husbandry. If only a part bred buck, with a few ewes, were commenced with by every one that has the means, it would be an immense advantage not only to owners but to the country.—*South Western Farmer.*

The Compost Heap.—Begin with the arrival of the first favorable weather to gather materials for compost. Don't let a particle of matter capable of being converted into food for plants slip through your fingers. Manure is the farmer's capital—the wand by the favorable instrumentality of whose mystic and occult operations, he diversifieth the surface of the earth with the smiling beauties of vegetation, and causeth the waste places thereof to bloom, and the desert to blossom as the rose. "Give me a sufficiency of manure," said an elderly farmer to us, recently, "and I can work out a living in any country, and from any soil." The merchant must have capital—the mechanic must have instruction, materials and tools, and the farmer whose heritage is the broad fields and fertile valleys of his "mother earth," *must* have manure. It therefore behooves every one to be attentive to this grand point, and to gather up the means of enriching and rendering fruitful the soil, the products of which sustain his life.

No one who has not made the experiment will be able easily to appreciate the importance of attending, practically and *habitually* to the rules thus hastily laid down. Let every one, therefore, be sedulous in his efforts, and our word for it, he will never have occasion to deprecate the results.—*Maine Cultivator.*

CATTLE FOR THE SOUTH.

Messrs. Editors—I should be pleased to learn through the Cultivator, your opinion of the relative merits of the Devon and Ayrshire breeds of cattle, as best suited to the South. The Durhams will not suit this latitude, (Charlotte, N. C., and a light soil.) The object is principally butter and beef, and sometimes for the yoke.

A."

We wish to answer the question of our correspondent, in part, by asking another. Has "A." ever tried the Durhams, and satisfied himself they will not do in that latitude? The Durhams require good feed it is true, and no breed will do well without it. Devons and Ayrshires must have feed, or they will make neither beef or butter. The soil may be light, but if made rich it is precisely the soil for corn and lucerne, and if a little marl or clay should be added, clover would doubtless succeed admirably, and with these, Durhams we imagine would do well in any latitude.

If experiments properly made, have proved that the Durhams will not succeed, then for all the purposes mentioned by our correspondent, we should prefer the Devons. For beef and for the yoke, there are few if any breeds superior to the Devons, and if not in general equal to the Short Horns or Ayrshires for milk, still we have known some excellent milkers among them. The Devons are hardy, walk quick and lively in the yoke, and when fed make beef of exceilent quality. For milk or butter alone,

the Ayrshires would doubtless be superior to the Devons, and are indeed equalled by few breeds in this or any other country; but where the beef and aptitude to labor are to be taken into account, we think the Devons must have the preference.—*N. Y. Cultivator.*

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

SILK CULTURE.

We take great pleasure in giving place to the letter of Mr. ERNEST, (page 82,) and although we doubt not he only designed to have us make an extract from it on the subject of the culture of silk, we prefer to give it entire, because it affords us an opportunity to offer a few remarks on a subject of vital importance to us as the publishers of an agricultural periodical, and to urge the necessity of fostering our own domestic literature in every department of science and the arts. The feeling of patronising papers from home is too commonly indulged by most of our people, and applies to newspapers, periodicals, &c. &c. in every department of literature and science as well as agriculture. This is one of the most powerful obstacles at the South to every enterprise of the kind. We are too prone to regard those things which are most difficult to be obtained, and to possess something of a foreign air, as of the most value—while if the Southern people would bestow one-half the patronage on their home periodicals and papers that they do upon those abroad, they would place them above contingencies, and enable the publishers to present papers of equal merit in every particular. This feeling is strikingly illustrated in the patronage which is given by our planters to the agricultural periodicals of the North;—for although many, and indeed quite all of them, are conducted with singular ability, much of the matter which they contain is of little value to our planters, because inapplicable to our climate and productions. Nevertheless many of them indulging the feeling that nothing can be accomplished as well at home as abroad, prefer to patronise such papers to one exclusively devoted to Southern agriculture. We make no complaint at these things, for we expect no man to take our paper as a matter of courtesy; but we have observed for such a long series of years, the existence of this feeling throughout the country, that we could not forego the opportunity which the letter of Mr. Ernest has afforded us, to allude to a subject of such vital importance to the whole newspaper and periodical press of the South. The maxim, "*Charity begins at home,*" is a good one, and there is no business in which it should be more rigidly observed, than in the support to be extended to the press. Foster and cherish then your own domestic literature, and you will not only give a new impetus to the improvement of the age in morals, religion and science, but you will escape the reproaches so often heaped upon the South, of the want of an elevated standard of home literature.

With these remarks, (for which we shall doubtless be charged as being influenced alone by self-interest, but which we heed not,) we commend to the reader the communication of Mr. Earnest on the culture of silk, together with his sound, common sense, practical views upon that greatest of all evils, because generally the immediate and certain precursor of every vice, IDLENESS.

CURING SWEET POTATOES.

In this number we present to the reader the communications of two practical planters on the subject of curing this delicious esculent, both of whom have been very successful in preserving them sound until late in the spring. From our own observation, however, we incline to the opinion that the plan adopted by "A PLANTER" is decidedly preferable, and will be much more certain in all seasons to keep the potatoes sound, although we are well aware that many practical men prefer the heap after having tried the house. This, however, we are disposed to think has resulted rather from the defects in the construction of the house, than any other cause—an opinion which we have long entertained, and which the article of "A Planter" has materially strengthened. It is very apparent to our mind, and we doubt not will be to Mr. POWERS, that his house was entirely too close, excluding as it did that free circulation of air which "A Planter" regards so necessary to the preservation of the potato.

In reply to the enquiry of Mr. Powers, "whether any experiments have ever been made to test the practicability of making sugar from sweet potatoes," we reply, that none has come within our observation, nor have we any where seen or heard of a single experiment of the kind.

ANONYMOUS CONTRIBUTORS.

We should certainly feel obliged to our contributors to allow us to give their real names to our readers as the authors of their respective communications. We are not ignorant of the fact, that many men feel some delicacy in appearing before the public in any other than an assumed name; and however proper the indulgence of such a feeling upon some topics of discussion, it is decidedly improper in all communications pertaining to agriculture. We might give numerous reasons for this opinion—but it were needless. No planter hesitates to communicate, in his daily intercourse with his neighbor, the result of his experiments in every department of his business, and give them as his own experience—then why not let the public know to whom they are indebted for whatever is communicated through the medium of the press? Such a policy would certainly give the reader greater confidence in the experiment and he would be much more disposed to test its value when given over a real name than a fictitious one. We therefore hope our contributors will generally adopt the practice of giving their real names.

CATTERPILLARS.—An English agricultural paper says, that a gardener at Glasgow practices a mode of destroying catterpillars, which he discovered by accident. A piece of woollen rag had been blown by the wind into a currant bush, and when taken out was found covered by the leaf devouring insects. He immediately placed pieces of woollen cloth in every bush in his garden, and found next day that the catterpillars had universally taken to them for shelter. In this way he destroys many thousands every morning.

SALT FOR CUT WORMS.—We have seen it highly recommended in various agricultural publications to sprinkle salt plentifully over the beds in a garden, infested by cut worms. We have never tried it for this purpose, but should it fail to drive off the cut worms, it will act as a powerful stimulant to plants, and hasten them on to maturity more rapidly.—*Planter.*

ON THE ROTATION OF CROPS.

GENTLEMEN—A plain farmer who has been an attentive observer of the success he has met with in his career; of the influence of seasons, with the same crops, will, I fear, be led to believe much of the labor of those who write so much about the absolute necessity of rotation, poisonous excretions of plants, &c., might have been saved; in reality, he believes the most of it is utterly futile. That soils will deteriorate, there is no question, even if there be rotation; that manure would be advantageous we doubt not; but there has been so much said about this matter, that it tends to keep still farther off the incredulous. I would therefore propose a medium course, and point out some advantages that many have seen and will appreciate. But first, we will examine our natural forests, where the white oak, and sweet gum, &c. have grown for ages, without rotation, without the poisonous excretions preventing their growth, to the age of 147 years, if the rings of the growth of the white oak are a criterion of age. We find in our forests, the land to improve, by a continued fall and decay of the leaf, notwithstanding the crop is yearly made, and is continuous. We also find fence rows to become enriched, in a surprising degree, (to the careless observer) notwithstanding it produces a yearly crop of grass and weeds; and yet here is no rotation nor would we suppose poisonous excretions.—We know that in some of the great wheat growing portions of our country, that wheat has been grown consecutively for almost half a century. We know that fields in this south western country have grown cotton for years and years—and yet we are told of rotation and poisonous excretions. Sweet potatoes, cow peas and pinders, will undoubtedly enrich land, though planted for a series of years, and though I have known the two first planted several years on the same land, I heard of no decrease in product. The question then is, how can we imitate nature, and yet obtain the advantages of culture? This will bring me to the medium course I propose to point out, and at the onset will show what I said, many have seen and will appreciate. After having planted a field two years in cotton, a crop of corn can be much easier cultivated, owing to the necessity of keeping the land clean; and if the same labor be given to the corn as usual, a better crop is the result; their interest would point out to plant corn; though when cotton be changed, it is much more difficult of cultivation. If after corn, oats be sown, and allowed to be fed off on the land, or if cut, and stock not permitted to graze—the ensuing year if in corn or cotton either, will be better—these are all facts. And the advocates

of the rotary system will claim it as "a feather in their cap"—but let them look at the returns made some years since, published in the American Farmer, I think, from a small piece planted in wheat, which astounded all farmers around there—I cannot now refer to page and volume as I forget*—but it was owing to an ample return made to the land of stable manure. I would then say to every farmer, give your land food, suited to its digestive organs, if you would expect it to feed you in return. This may be easiest done, by a change of crops, and I doubt not every judicious farmer will adopt it to a greater or less extent. Many will ask why object to rotation and yet advise it? My reason is, that we are told a continued succession of crops is ruinous, and rotation beneficial; whereas, there are many who think as the old coffee drinker said of coffee—"If it is a poison, it is a very slow one, for I have been using it 70 years,"—and consequently pay no attention to what is their interest. I verily believe, if a field of good lively level land, were well cultivated, all the stalks and seed ploughed in yearly four to six inches deep, that it would improve in quality and yield for a century, and I appeal to the woodlands and fence rows and briar patches, for proof. We cannot imitate nature, in keeping ground shaded, and taking nothing off—but I believe the culture, if properly pursued, would come so near it, that there would be improvement. I am an advocate for rotation, and urge it, for the reason assigned, not on account of poisonous excretions at all—which sounds to me very much like forcing a child to tell the truth, least the devil catches him, rather than inculcating into him the intrinsic merit of truth, its beauty, and if no other reason, the interest he has for so doing.

The great desideratum of farming I look on it is to make the most out of one's labor—and to do this effectually, we should make it a primary object to endeavor to improve the soil, for plague and pestilence or disasters may sweep off the gain if taken from the land, but if returned to mother earth, she indulgently returns us twofold. I would then define good farming to be, a steady improvement of the soil, with the greatest yield. Nor do I by any manner of means yield to any man a preference of being a "best farmer," because he adds the fastest to his property, because he may scratch on and waste 10 to 20 thousand dollars worth of land, to buy 10 to 20 thousand dollars worth of property, whereas his neighbor has but half or only one-third as much property, and has kept his land and stock, &c. &c. up in a condition to sell for prime cost, even at a moment. This has been unfortunately the mode of judging in all our slave holding country, which has brought us to the necessity of manuring or rotation, if we would do as well as we have done.

In connection with manuring or rotation, I would urge the great advantage of thorough deep ploughing—I mean by this, that every particle of earth be turned over as early in the year as is possible, from 4 to 6 inches deep; believing from trials made for the three past years, that deep ploughing will, unaided, give a very handsome return. I did sow corn last year, on the same soil precisely, that yielded from five to seven bushels more per acre, than on land some three to five years later in cultivation—the only difference was deep and thorough ploughing for two years—on which I will plant cotton this year, and expect a yield of 1 to 200 lbs. per acre more, it being old land on which some eight or nine crops of cotton have grown out of thirteen or fourteen.

W. M. PHILIPS.

Tennessee State Agriculturist.

*Since writing the above, I have referred to my bound volumes and files of American Farmer, and find the crops of wheat grown on the same land for "five successive years" was by "Adam Wharm, Esq. of Elkton, Md.. On the 276th page of the present volume, the editor remarks, there are two features about Mr. Wharm's culture that go to astound us, "such heavy crops" and the "success" attending his using "stable manure." I allude to this case in point, particularly, because there was a succession of the same crops, a yield that even for one year was very great in that country, and there was manuring.

AGRICULTURAL HYMN.

Great God of Eden! twas thy hand
That first clad earth in bloom,
And shed upon the smiling land
Nature's first rich perfume.

Fresh at thy glance the flowers sprung,
Kissed by the sun's first rays—
While plain, and hill, and valley rang
With life, and joy, and praise.

Gods of the clouds! thy hands can ope
The fountains of the sky,
And on the expectant thirsty crop,
Pour down the rich supply.

The farmer, when the seed time's o'er,
Joys in the mercies given—
Thinks of thy promised harvest's store,
And smiling, looks to heaven.

God of the sheaf! to thee alone
Are due our thanks and praise,
When harvest's grateful labor's done,
On plenty glad we gaze.

Then shall our thoughts on Heaven rest,
Thy grace we will adore,
And thank that God, whose money's blest
Our basket and our store.

Selected.

THE TIMES.

The low prices of agricultural productions, and the severe pecuniary embarrassments of the present time, together with the slight prospect of improvement for the future, have caused a feeling of despondency among many farmers which is much to be regretted, and a little reflection will show is very unwise. It is true that the prices of produce offer but little reward for labor, and the prospects for the future are by no means flattering; but what then?—shall we settle down in gloomy despondency, and resign ourselves and families to inglorious poverty and ignorance, while Nature and Providence, and the wonderful discoveries of the age call upon us to put forth new efforts, and awaken new energies of the mind—to call in the light of science to our aid, and combine it with experience, skill and industry?

When wheat was $1 50 and corn $1 per bushel, pork and beef $5 per 100 lbs., and other things in proportion, the most unskilful and negligent farmer could hardly fail of making profit, and *then*, if ever, was the time we could best dispense with the aid of science and agricultural experience. But now, with the increasing competition of the west, and the prospect of continued low prices, *is the very time* when every farmer has need to AWAKE, and avail himself of all the knowledge and experience, and all the improvements and discoveries which the past has developed. In short, now is the time when the very perfection of art should be combined with science and sagacity, in order to ensure success and profit in agriculture.

The farmer has now more than ever before, need to understand the nature and condition of his soil, and the best means of renovating and enriching it; the nature and operation of mineral, animal and vegetable manures, and their adaptation to different crops; the extent to which labor saving machines can be introduced into his business, and, in short, *how to produce the most and the best* of every thing with the least possible expense and labor.

How mistaken, then, that policy which induces farmers to deprive themselves of the means of information, from motives of pretended *economy!* Thousands of farmers, the past winter, refused to purchase a book, or even to subscribe for a paper devoted to their interests, because, forsooth, "the times were so hard that they must practice economy!" Out upon such economy! we say. It is like self-righteousness, the more you have of it the worse you are off. These men have spent their long winter evenings and stormy days moping in the chimney corner and whining about hard times, while they ought to be storing their minds with science and useful knowledge, thereby increasing their powers and means of success. And now reader, if "thou art the man," we beg of you to reflect on this subject, and see whether you are practising wise economy, and if thou art not the man, carry this paper to your neighbor and ask him to consider the matter, and give you his opinion.

New Genesee Farmer.

PROPER AGE FOR HEIFERS TO BRING CALVES.—A Roxburg subscriber asks our opinion as to the age for heifers to bring their first calf. He suggests that we injure our stock by letting the heifers bear too early, and that three and a half or four years would be a better age than an earlier one.

We think if the object is to raise large cattle the heifer should come to her full growth before she is admitted to the cow family. But if the great object is milk or butter—if it is desirable to raise the greatest quantity possible in proportion to the weight of the cow and to the food she consumes, the heifer should come forward early. She should have a calf at the age of two, or two and a half, if she has been well kept. Her milk vessels will then be large in proportion to her limbs. Small cows almost always give more milk, in proportion to size, than large ones.

Massachusetts Ploughman.

AUGUSTA MARKET.

TUESDAY P. M., May 23.

Cotton—Our market remains quite inactive. The transactions since the accounts have been very light. A few sales have been made at a decline of from ⅛ @ ½ cent from the highest rate. The quantity offering is very limited, and although our stock is large, not more than one-third in store is on planters' account, the balance is held by our home speculators.

Money—Exchange on all the northern cities, Savannah and Charleston is abundant at par. Central Bank notes are in good demand at from 18 @ 20 ℔ cent discount, and a large amount may be sold at a less rate than our lowest figures. State 6 ℔ cent Bonds are much enquired for. Alabama bank notes can be sold for 15 ℔ cent discount.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., JUNE 7, 1843. No. 12.

COMMUNICATIONS.

DECATUR COUNTY, GA., May 15, 1843.

Messrs. JONES—I have been sometime thinking of sending you some of my ideas in a crude state as they are, for you to refine them, but as I write under a fictitious name, I could not well afford to pay the postage and then not see my name in print; but after seeing your suggestion of the 31 instant, for planters to send in their plans for keeping sweet potatoes, I could with stand the temptation no longer, and as I have been a good potato grower, keeper and eater, I will give you my plan for making and keeping, which differs from Mr. McKinley's some. I think mine the better way, as I cannot conceive how he gets his potatoes out of the ground after he makes them, which he tells us nothing about. But to the text.

In the last of February or first of March, with a good season in the ground, I break up well, then lay off rows four feet apart, and throw up a bed of four furrows, with turn plow, same as for planting cotton, only I am more careful to bed as high as possible; then, after first rain, run a scooter furrow in middle of bed and drop the potatoes in it from 12 to 18 inches apart, and throw up with turn plow as before. When up, side with scooter or coulter, and throw up balance with turn plow; afterwards use the turn plow altogether until the vines run so as to be in the way too much, then, when a good season is in the ground, draw up the earth under the vines so as to make a tolerable ridge, and you will have a mellow bed, and the the potatoes will be so deep in it as not to be injured by drouth worse than the surface culture, with the advantage that you have the mould thrown next the potatoes, and a ridge to plow down to get the sweet things, which do with a long scooter. If there is no danger of frost, let them lie in the field all night to get cold. Have an inch or two of the surface scraped off at the place of banking, so as to form a circular ridge on the out edge, and fill with potatoes—making the hill as sharp at top as the potatoes will lie. Lean corn stalks, clear of shuck, cut the right length, so as to reach from the ground to top of hill.—Lean them up from six to eight inches apart at bottom, so as to keep the bark from the potatoes. Cover with pine bark, and then with earth the thickness of the breadth of a hoeblade, laying it up with the edge of the hoe next the hill. Have the bark so as not to reach beyond the top of the potatoes, which will leave an opening of near a oot in diameter at top, for the escape of the heat while going through the sweat. Cover the top with a piece of bark, leaving it in its natural shape, (concave side down,) to turn off the rain, and a little dirt on top of it to keep it there. There are but two months out of the twelve but I have potatoes, and not a few kept for a rarity, but as many as my negroes and all will destroy, by following the modus operandi above stated. If you think it worth a place in your Southern Cultivator, after pruning and pointing, give it, if not, throw it in the fire, as I do not wish to see any thing bad (not even my own) in it.

Mr. McKinley's theory of mixing earth with potatoes, I think is better in theory than pactice. I have not a doubt but they would keep well, but it is a well known fact that potatoes never sweeten until they are taken out of the earth and put where they keep dry—the dryer you keep your potatoes the sweeter they will be.

I have tried pine straw instead of stalks in banking, but it retains too much of the moisture generated in the bank, and causes the potatoes to rot. I am of the opinion that pine sticks split small, would be better than stalks to lean around the bank.

Yours, &c. AGRICOLA, JR.

P. S. To keep beef fresh for eating, sprinkle it over with corn meal and hang it up, and you need not fear the flies. As simple as it is try it.

CRACKER'S NECK, GREEN CO., GA., May 15, 1843.

Messrs. JONES—In the last Cultivator I discover an answer to an enquiry made by Mr. Penniman of Col. McKinley, of Lexington, as to the best method of keeping potatoes through the winter, and as it seems that the Colonel's modus operandi proved ineffectual, I will give you my mode, which has never failed in one instance with me, last winter (which was very fatal) not excepted.

After digging my potatoes, I raise a mound of loose earth, say some three or four inches above the common level, upon which I pile my potatoes as snug as possible, say 40 or 50 bushels to the bank, more or less, it matters not. I then cover them completely with corn stalks, placed straight from the base to the top of the hill, and cover all up with about three inches of earth. Some leave air holes at the top, but I find, from experience, that it is best to prevent all accession of air to the potato.

I like Col. McKinley's mode of raising them very well, and have adopted it this year. I see no reason why it should not succeed admirably. I have generally planted in the common way, and have raised enough to last the year through. I have now plenty of as fine as I ever saw.

My method has been, at the opening of spring to raise my potatoes from the banks above described, and sun them until perfectly dry, and then place them in an upper dry room. They have always kept well and retained all their good qualities during the summer.

Respectfully,

JOHN D. COPELAND.

RESPONSIBILITIES OF AMERICAN WOMEN.

The succes of republican institutions, as is conceded by all, depends upon the intellectual and moral character of the mass of the people. If they are intelligent and virtuous, democracy is a blessing; but if they are ignorant and wicked, it is only a curse, and as much more dreadful than any other form of civil government, as a thousand tyrants are more to be dreaded than one. It is equally conceded, that the formation of the moral and intellectual character of the young is committed mainly to the female hand. The mother forms the character of the future man; the sister bends the fibres that are hereafter to be the forest tree. The wife sways the heart, whose energies may turn for good or for evil, the destinies of a nation. Let the women of a country be made virtuous and intelligent, and the men will certainly be the same. The proper education of a man decides the welfare of an individual; but educate a woman, and the interests of a whole family are secured.

If this be so, as none will deny, then to American women, more than to any other on earth, is committed the exalted privilege of extending over the world those blessed influences which are to renovate degraded man and "clothe all climes with beauty."

No American woman then, has any occasion for feeling that hers is a humble or insignificant lot. The value of what an individual accomplishes, is to be estimated by the importance of the enterprise achieved, and not by the particular position of the laborer. The drops of heaven which freshen the earth, are each of equal value, whether they fall in the lowland meadow or the princely parterre. The builders of a temple are of equal importance, whether they labor on the foundation or toil upon the dome.

Thus, also, with the labors which are to be made effectual in the regeneration of the earth. And it is by forming a habit of regarding the apparently insignificant efforts of each isolated laborer, in a comprehensive manner, as indispensible portions of a grand result, that the minds of all, however humble in their sphere of service, can be invigorated and cheered. The woman who is rearing a family of children, the woman who labors in the school room, the woman who, in her retired chamber, earns with her needle, the mite which contributes to the moral and intellectual elevation of our country; even the humble domestic, whose example and influence may be moulding and forming young minds, while her faithful services sustain a prosperous domestic state—each and all may be animated by the consciousness that they are agents in accomplishing the greatest work that was ever committed to human responsibility. It is the building of a glorious temple, whose base shall be co-extensive with the bounds of the earth, whose summit shall pierce the skies, whose splendor shall beam on all lands; and

those who hew the lowliest stone, as much as those who carve the highest capital, will be equally honored, when its top stone shall be laid, with new rejoicings of the morning stars, and shoutings of the sons of God.—*C. E. Beecher.*

Whether rich or poor, young or old, married or single, a woman is always liable to be called to the performance of every kind of domestic duty, as well as to be placed at the head of a family; and nothing short of a *practical* knowledge of the details of housekeeping, can ever make those duties easy, or render her competent to direct others in the performance of them.

All moral writers on female character, treat of domestic economy, as an indispensible part of female education; and this, too, in the old countries of Europe, where an abundant population and the institutions of society render it easy to secure the services of faithful domestics.

All female characters that are held up to admiration, whether in fiction or biography, will be found to possess these domestic accomplishments, and if they are considered indispensable in the old world, how much more are they needed in this land of independence, where riches cannot exempt the mistress of a family from the difficulty of procuring sufficient aid, and where perpetual change of domestics, renders perpetual instruction and superintendance necessary.

Since, then, the details of good house keeping must be included in a good female education, it is very desirable that they should be acquired when young, and so practiced as to become easy, and to be performed dexterously and expeditiously.

The elegant and accomplished Lady Mary Wortley Montague, who figured in the fashionable, as well as the literary circles of her time, has said, that "the most minute details of domestic economy become elegant and refined, when they are ennobled by sentiment;" and they are truly ennobled when either from a consideration for a parent or love to a husband. "To furnish a room," says the same lady, "is no longer a common place affair, shared with upholsterers and cabinet makers, it is decorating the place where I am to meet a friend or a lover. To order a dinner is not merely arranging a meal with my cook, it is preparing refreshment for him whom I love. These necessary occupations, viewed in this light by a person capable of strong attachments, are so many pleasures, and afford her far, far more delight than the games and shows which constitute the amusement of the world."—*Young Ladies' Friend.*

On the Cultivation of the Raspberry.—The plants are frequently set out in light and poor soils, crowded together, left untrimmed, choked up with a profuse growth of weak stems, and what little fruit they produce is nearly dried up, from the arid situation in which they are placed. On the contrary, in cool, deep and moist soils, in a sheltered and partially shaded place, the plants throw up suckers to the height of six or eight feet, and produce a profusion of large, handsome, and well flovored berries. So well assured are the most eminent English cultivators of the raspberry of its love of a cool and moist soil, that some writers have strenuously recommended the use of bog earth and rotten leaves, in the place of the richest loam. We are well assured that the many complaints which are made of the meagre produce of many raspberry plantations may be attributed wholly to the light and droughty soils in which they are often planted.

A cool aspect is of material consequence, and to secure this the north side of a fence or trellis, which will form a screen from the sun, is the most favorable: on the north side of a shrubbery or row of fruit trees is also a suitable place. If neither of these situations is to had, an open spot in the garden may be chosen, always being careful to avoid the south or east side of a fence. A temporary shade may be effected in the open garden by planting a row of running beans on the South side.—*Hovey's Mag.*

CORN STALK SUGAR.

It will be recollected that we published a communication in November last from Mr. W. C. Rogers on the subject of the manufacture of Sugar from Corn Stalks. The letter below from the same source further explains the process, and more fully describes the mill used for extracting the juice from the stalk:

Caledonia, Henry County, Tenn.,
March 24, 1843.

Dear Sir: I have received various letters asking information about the construction of Mr. Vaughan's Mill for making sugar from Corn stalks, the manner of cultivating the corn, process of manufacture, &c. To save the trouble of future enquiries, I send you this communication, which you will oblige me by inserting in the Banner.

The mill is composed of two upright rollers, one 58 inches in length, the other 46, which are secured by a strong frame 8 feet long, 3 feet wide and 30 inches high; 17 cogs on one roller work in an equal number of cogs in the other, and are moved by a sweep; the short roller has a body 24 inches long, 20 inches diameter, a neck piece at the top to be inserted in the frame 8 inches long, 10 inches diameter, a cog space immediately under the top neck 6 inches long and 17½ inches diameter, and a neck at bottom 8 inches long, 10 inches diameter, making its entire length 46 inches. The long roller is of the same dimensions, with similar body, neck piece and cog pieces, with the exception that 12 inches are added to the top neck of the long roller for the insertion of the sweep.

In grinding, the stalks are passed by hand between the rollers, and the juice is squeezed out on their passage. If not sufficiently pressed out on the first passage, they are returned a second time between the rollers. The juice is caught by the bottom piece of the frame, which is three feet wide like a platform and sloping on one side so as to make it run out into a vessel placed there for the purpose.

After the juice is obtained, it ought not to stand more than an hour for fear of fermentation. It is then placed over the fire and as it begins to boil carefully skimmed. When boiling the scum should be rapidly removed as it rises.

If some of the syrup can be taken between the thumb and finger and when moderately cool a half inch or inch long can be drawn, it is thought boiled sufficient. If you wish only to make syrup it is not boiled quite so much. To make it grain into sugar a few spoonfuls of limewater has been recommended.

The only fixtures used by Mr. Vaughan in boiling were a common ten gallon pot and three other pots of about the same size. The process is neither intricate nor tedious. Corn standing in the field may be cut, ground up and converted into elegant syrup in three or four hours.

From the foregoing description it will be seen that the principle upon which the mill is constructed is the same as that of Mr. Webb's of Delaware, as described in the June number of the Albany Cultivator for 1842, with the exception of the dumb returner or third roller, which is not found in Mr. Vaughan's mill. The process of boiling and manufacture is the same.—Neither the plan of the mill or process is new; mills of a similar description have been used by planters in the lower part of Georgia for making sugar and molasses for the last twenty years. To Mr. Webb of Delaware, is, however, due the great credit of substituting Corn stalks for canes.

Is it profitable? is a frequent question. Mr. Vaughan thinks he can make sixty gallons of molassess per acre, which, at present prices retailing in this neighborhood, would yield a profit of 25 or 30 dollars.

When the manufacture becomes common in the West, such is our unbounded capacity for making corn, of course the profits would be nominal. But if only made for family use, it will be a great saving, and become, when we get in the way of making plenty of molasses, an actual blessing to children and negroes. Three days are sufficient to grind up and make 60 gallons of molasses, and the work will come on at a season when the time can be easily spared. The refuse juice is alone valuable for making a most grateful beer and good vinegar.

As to making sugar, Mr. Vaughan failed in the last year, but will plant 15 acres the present spring and "try again." The supposed causes of his failure I gave you in my communication of October last.

The corn I had like to have forgotten to mention, is the common sort of corn, planted and cut in the same manner as any corn, with the exception of removing the shoots as they appear. Mr. Vaughan cut his corn as the fodder began to ripen, at which time he thought the juice would be most apt to be matured; of course he stripped off the fodder before he cut it. Cost of Mill, $6.

SUGAR FROM CORN.

To the Editor of the Ohio State Journal:

Sir—When the fact was announced that corn stalks were quite equal to the cane for the production of sugar, it was natural to suppose that our farmers would immediately avail themselves of so great a discovery to increase the profits of their labor. But we find that nothing but ocular demonstration will induce people, in such times as the present, to engage in any new enterprise, however feasible of promising beneficial results. It was with that view I put up a mill last season for the purpose of making a trial on this subject, and the issue of my experiments prove all that had been before stated to be true, and more, for the fact was established to my satisfaction, that sugar, or at any rate, first rate molasses, may be made from corn stalks, after the corn has come sufficiently to maturity to be fed to swine.

I found that corn stalks contained vastly more saccharine mattert han I had supposed possible. The expressed juice indicated nine degrees of the sachrometer, and one gallon produced more than one pound of sugar, which is more than is usually made from the Cane.

I obtained last season one hundred and fifty pounds of molasses, but only a small part of it granulated, owing to my letting the ears of corn ripen too fully on the stalk, or to an imperfect method of manufacture, or to both. But that which did not granulate was an excellent article for family use, of a most delicious flavor, and, as we found by experience, very wholesome.

I have no means of knowing how much sugar can be obtained from a given quantity of ground, but I do know that the product will be abundant, and I firmly believe that the time will soon arrive when this indispensable article of domestic economy will be produced among us.

The mill that I used to crush the stalks and extract the juice, was made somewhat like a cider mill—the rollers are eighteen inches in diameter, (two feet would be better,) twenty inches in length, made of wood and connected together with cogs; the gudgeons at the bottom are made of iron, two inches in diameter.

One horse turns the mill with ease. A wooden mill that any carpenter can make, will be sufficient for a whole neighborhood; but when the business is conducted upon a large scale, iron cylenders would be preferable.

In straining, clarifying and boiling the expressed juice, I designed to follow the directions of Mr. Webb, which have been so fully published that they need not be repeated. I made a mistake, however, and used too much lime, which is indicated in the sample I sent you. I am now of opinion that one spoonful of lime water of the consistency of thin cream is sufficient for a gallon of juice; this however can be best determined by experience.

The boiling was done in iron kettles hung over a fire, out of doors, and I found much difficulty in the burning of the syrup on the sides of the kettles, by which a part was decomposed and became like wax, and this again mixing with the whole mass undoubtedly tended to prevent crystalization. Molasses may be made in this way, but for making sugar suitable boilers

should be set in brick work so that the fire shall only come in contact with the bottom.

The expressed juice of the maize, like that of the cane, is impure when it comes from the mill, as a portion of the solid parts of the stalk necessarily mixes with the liquor in the operation of obtaining it, and these must be separated in order to ensure good results. The object of using lime is to effect that purpose and to neutralize the acid the juice is supposed to contain.

And here I will express an opinion that I have formed in part from observation, and that is, that if the expressed juice is suffered to stand a certain time in a large open vessel, after it comes from the mill, the heavier parts of the feculencies will fall to the bottom, and the lighter will float on the surface, and when the liquor is drawn off, it will be nearly free from impurities. Should this prove to be the case, a great object will be gained with little trouble; the only thing that can prevent success in this mode of treating the liquor, will be the commencement of fermentation—this I think will not occur in our climate, at the season we should make sugar.—Towards the latter part of my operations, I adopted the course above mentioned with my syrup: what I boiled into syrup in one day, I let stand to settle till the next before being made into sugar at all.

As to the method of planting corn for this purpose, I have not much experience. The small patch I planted last year was done late, so that it did not come to maturity; but I intend to plant some this year and have the rows about three feet apart, and drop the corn in drills from one to two inches apart.

And now, Mr. Editor, I must take the liberty to urge you to call the attention of your readers to this important matter as planting time is approaching, and there ought to be thousands of acres devoted to this culture this spring.

Yours, &c., S. BALDWIN.

Cattle and horses readily eat the refuse of the mill. By permitting it to cure and adding a little salt to the heap, it makes first rate winter fodder. Nothing, either of leaves, tassel or stalk is lost. All is saved.

NUTRITIVE PROPERTIES OF DIFFERENT CROPS.

Our estimate of the nutritive value of different kinds of food is generally of a very vague and indefinite character; the ordinary farmer can estimate the effect of different supplies only by long and close observation; and indeed the health and growth of his stock is liable to be effected by so many causes, over and above the food they eat, that the result of his observations, even when closely made, may be far from satisfactory. It would be a great thing then, if by chemical analysis we could discover exactly the properties of different kinds of food; in producing for market, no such investigation is required, the best test of a saleable product being its market price; but a farmer wants to know whether to cultivate an acre of land in potatoes, or carrots, or sugar beets, or whether old-fashioned Indian corn is not more profitable than any of them. He can calculate the expense of cultivation of each; he can estimate the quantity of product in each, and if he could ascertain the comparative nutriment of each, he could at once draw a thorough comparison between them.—Vegetable substances, it has been long known, consist, invariably, of certain constituents, as gluten, albumen, gum, starch, water, salts, &c. in different proportions. Some of these principles are known to be more, and some less, useful in supplying the animal economy: the gluten, albumen, &c. it is said are converted by the vital functions into *flesh*, whilst the gum, starch, sugar, &c. are only useful in creating *fat*. It would seem then, that we would have only to ascertain the proportions of each constituent in a given substance, which chemical analysis will always do, to tell exactly for what purpose it is adapted. Accordingly, scientific men, from time to time, have endeavored to obtain this estimate by analysis: but unfortunately not always with the same results. Indeed, we presume, that the constituents of a vegetable will vary, to a certain extent, with the climate and soil in which it is raised, and we presume too, that these constituents may, in a measure, be differently appropriated by the digestive organs of different animals. Moreover, so intricate and complex is the chemical action of compound substances, especially when subjected to vital action, that nothing can be predicted without an *exact* knowledge of *all* the constituents present in any given case. Although these circumstances, unfortunately, render the deductions from chemical analysis even more uncertain than those drawn from common observation, yet the use of both methods may lead to more certainty than could be obtained from the sole application of either. We give to our readers, therefore, the latest estimates of the celebrated French chemist, Boussingault, on some important points. He found that the nutrative properties of

100	bus.	beans	was	equal to	120	bus yellow peas.
100	"	"	"	"	191	" wheat.
100	"	"	"	"	200	" rye.
100	"	"	"	"	232	" barley.
100	"	"	"	"	240	" Indian corn.
100	"	"	"	"	1096	" potatoes.
100	"	"	"	"	1361	" carrots.
100	"	"	"	"	1446	" cabbage.
100	"	"	"	"	2383	" turneps.

Dr. Dana, of Massachusetts, has also lately made a comparative analysis of corn, ruta baga, and potatoes, from which he has deduced the following table:

	100 lbs of Corn.	Ruta Baga. fresh dug.	Potatoes. fresh dug.
Contain of flesh forming principles: gluten, albumen, &c.	1.26	1.	2.07
Fat forming principles: gum, starch, sugar, woody fibre, oil, &c.	88.43	13.	24.34
Water,	9.	85.	72.
Salts,	1.31	1.	1.39

For the growth of animals and the formation of flesh, it will be seen, that Dr. Dana places a very low estimate upon Indian corn; whilst he esteems it very highly for the formation of fat. Without drawing this distinction between fat and flesh, Boussingault estimates its nutritive properties infinitely above both potatoes and turneps.—*Southern Planter.*

CHARCOAL AS A MANURE.

I have had some experience in the use of charcoal as a manure, and fully concur with Mr. Hepburn in its being a valuable and durable manure; but whether it might not require so great a quantity of coal in order to increase the productiveness of the soil as to make it expensive, I have my doubts; but I am fully of the opinion that the coal dust left on the coal beds (or hearths, as Hepburn calls them,) and the dust or fine coal which may be found in large quantities about iron manufacturing establishments, and all places where there is dealing in coal, may be applied to profit as a manure.—The farm which I occupy was mostly cleared by coaling the timber, consequently these beds are numerous, and fourteen years I have tilled one or more fields, where there were more or less of those beds, and such places have never failed to produce as large crops as I could wish. These beds in consequence of the large quantities of fine coal left on the ground, and the dryness of the earth, produced by the fire or some other cause unknown to me, will not produce anything for several years, unless it is carted away; therefore in order to obtain a crop on any such places, and benefit other lands by the application of the dust and fine coal, carting becomes necessary. I applied two loads this season from a bed made last fall, and I think from the large growth of wheat straw produced where it was applied, and the present appearance of the grass, it is worth two-thirds as much as good stable manure. I have never suffered by the depredations of the corn-worm, where coal dust has been applied thoroughly as a manure, and as for its durability, there is no question; for, in my cornfield this year, there is one of those beds that was made twenty four years ago, and it has been either in grain or grass ever since. And did the rest of the field look as promising, I should be assured it would yield ninety or a hundred bushels per acre. I intend applying this dust thoroughly to my garden this fall, and if I thereby increase its productiveness, and destroy the habitations of worms, and other insects, that prey upon vegetation, I think I shall ba amply repaid for the outlay.

LEWIS EAMES.
Central N. Y. Farmer.

TANNERS' BARK.

Mr. EDITOR—I wish to inquire whether tanner's bark can be used as a manure? By favoring me with a speedy answer you will oblige,

Your's sincerely, CORTEX.

W———, March 10, 1843.

REPLY.—Bark fresh from the tan pit will destroy vegetation as readily as salt. If hauled into the cow yards, however, and suffered to remain a year or so, it will become valuable manure, and may be applied advantageously to soils of almost every kind. It operates mechanically, and is beneficial on lands naturally wet and viscid, and in which there is a superabundance or excess of clay.—*Maine Cultivator.*

Tan may be used fresh from the pit, if used sparingly, without doing any injury; if used in *excess*, it will, like salt, destroy vegetation. In moderation both are excellent manures. As an amender of a stiff clay soil, we know of nothing better than tanner's bark: when spread over cow yards or pig pens it is invaluable as an absorbent, and when, after a single season, it becomes mixed with the other substances it forms an excellent manure: when mixed in the following proportions, 200 bushels tanner's bark, 20 of lime and 50 of ashes, and suffered to remain a month or so in the heap, the mixture, after being turned over and thoroughly incorporated forms as good a manure as any farmer need desire to put on an acre of ground.—*Am. Farmer.*

ECONOMY IN FEEDING CATTLE.—Our worthy neighbor and ancient citizen, Mr. Jas. Boatwright, whose active mind scorns the repose so congenial to his advanced age, after a life of industry and usefulness, still finds pleasure in taxing his mechanical powers in order to be useful. He has recently invented, and has now in operation, one of the most complete and simple machines for grinding corn, either in the cob for feeding cattle, or for meal or grist, that we have ever witnessed in operation. The mill is formed with two common granite stones in an upwright position on a gudgeon connected with a wheel, to which is applied the power of a four horse steam engine that was formerly provided and is still used in his cotton gin manufactory for turning, and he is enabled to grind one hundred bushels of corn per day with the labor of one man to feed it! The whole is fitted up in the cellar of his gin shop. The corn and cob are both ground up together, and makes most nutricious food for cattle. By this process a saving of at least one third is made in the feeding of cattle. It is said to be superior to peas, and can be purchased at the mill for 37½ cents per bushel. Attached to the machinery is also another pair of stones which turns out as beautiful meal as we desire to use. Our fellow citizens will do well to avail themselves of the opportunity of purchasing this cheap food for horses and cows and corn meal for table use.

Columbia (S. C.) Chronicle.

SUBSTITUTE FOR CREAM.—Beat up the whole of a fresh egg in a basin and then pour boiling tea over it gradually to prevent its curdling. In flavor and richness this preparation closely resembles cream.—*Southern Planter.*

SALT YOUR COWS.—All cattle need more salt when they are first turned to grass than afterwards. Let them have access to it twice a week in May and June.

ADDRESS

Of Col. B. L. C. Wailes, (President,)

Delivered before the Agricultural, Horticultural and Botanical Society of Jefferson College, and a numerous assemblage of ladies and gentlemen, at Washington, Mississippi, April 23, 1843.

* * The first place in the primary production of those material objects suited to the wants of mankind, is assigned to the husbandman.—Contributing most largely to the necessities of all classes, he is the least dependent upon the labors or productions of others; and although this very independence may perhaps retard the progress of agriculture, by repelling or rejecting the adventitious aids of science, which are constantly accelerating and perfecting most other pursuits; still, the benefits conferred by agriculture, even in a rude and unimproved state, are so numerous and important, as to entitle its votaries to a high consideration, and insure them great respect. Few, it is true, are educated for planters, or receive that kind of mental culture the most suited to that pursuit. Many who pursue it, are learned to a degree calculated to adorn the most respectable and liberal professions; yet in their scholastic course, have gained little more, in reference to husbandry, than a few glimpses of pastoral life, gleaned from their early classics. Upon such, the influence of associations for the promotion of Agriculture, is not less salutary than upon the unlettered farmer. Nothing is better calculated to supply such defects of early education, and to stimulate a spirit of investigation and inquiry.

To a cultivated mind, imbued with science, how instructive, for example, is the contemplation of vegetable matter.

In every stage, from the gem of the seed deposited in the earth, the expanding leaves and opening flowers, to the maturing and ripened fruit, it excites surprise, and challenges admiration. In the season of returning life, when dormant nature, awakened from repose, reflects its cheerful smiles, warmed by the influence of the orb of day, the excited sap ascends. It circulates through innumerable fibres, courses thro' thousands of little tubes, or pores, too minute for the unaided eye, delicately, yet perfectly, organized and arranged, performing offices equivalent to veins and arteries in the human frame, extends through all the branches, and nourishes the unfolding buds. This circulation, or current, which in some plants can clearly be seen, with the aid of the microscope, forms the bark, and marks the age of trees, with a layer for every year. Banqueting in morning dews, the same warming and illuminating influence pencils a tint on every flower, and paints the ripened fruit. In this fluid, or juice, as various in color as in taste, the principal medicinal virtues chiefly reside. In some it is sweet; in others, acrid and corrosive, bitter or acid, aromatic or narcotic. The sugar maple, the cinnamon and the poppy, furnish some examples of these properties; whilst the dye-woods, the beet, and other vegetables, exhibit it in all the varieties of color. As a knowledge of the curious structure and wonderful functions of vegetable life is unfolded, the character and habits, the affinities and antipathies of plants understood, it may oft times be discovered that the prevailing system of treatment or cultivation, injudicious and attended by a wasteful expenditure of labor, in actually stinting and restraining their productiveness. A mind thus awakened and directed, will not rest content with observations on vegetable physiology alone. It will look further into the wide and interesting field of investigation, and explore the mysteries of Agricultural chemistry and geology, in quest of those laws and principles which must govern the various operations of the successful cultivator. To distinguish merely between a fertile soil and a poor one, will not satisfy such an inquirer. A thorough knowledge of the constituents of soils will be sought after, their properties and combinations investigated, and the proportions of the various elements of which these are composed, will best sustain, stimulate and mature the various plants, the objects of our cultivation and care, will be carefully examined. The very atmosphere in which they thrive, and the gases they inhale or imbibe, will be analysed. Chemical changes are continually going on in the materials in which the planter operates, and a failure to take advantage of them, from ignorance or neglect, occasions great losses. In proportion as the valuable or essential properties of the soil are taken from it, in its vegetable product, must it be restored in some form; and a knowledge of the best manner of applying and assimilating the requisite ingredients, and of promoting and regulating the proper chemical action, is among the most valuable acquirements of the the farmer. In such investigations, many of the most learned and judicious men of our age are actively engaged. At no former period has science contributed so extensively and beneficially to the cause of Agriculture; or has more important and valuable discoveries and improvements been made, than in the present day. That the abstruse and scientific principles from which these improvements have been deduced, should be understood, or even investigated by all, is not to be expected; nay, it is not necessary that they should. Many who deride such studies as idle and visionary, will nevertheless adopt, from the experience and practice of others, improved processes in cultivation and domestic economy, without troubling themselves with the rationale of their operation; and whilst loudly contemning the visionary studies of the scientific, be successfully, though unconsciously, demonstrating their value and utility—as much to their surprise, perhaps, as the plain farmer, who, whilst vaunting the merits of his favorite plough, (a miracle of perfection in his estimation,) found himself unconsciously ridiculing and undervaluing the studies and investigations in mechanics, of the very man who had invented and constructed it.

A system of cultivation, or some process connected with Agriculture, may sometimes be adopted by chance, or suggested by convenience. That such is the case, we have reason to believe. That it may not always be calculated to insure the best results, or have had its foundation on any known or tried principle or experiment which recommended it to use; yet it may become the prevailing system, almost universally adopted, and be long persevered in, with such tenacity as almost to preclude any modification or improvement. A discovery has recently been made, (I term it a discovery, for under the circumstances, it surely is little else,) which goes far to illustrate and establish this position.

The Cotton Plant has been cultivated in the Southern States for more than fifty years, and for a long period there has been no process more generally adopted and uniformly followed, than that pursued, in which the principle seems to be, to cultivate the greatest possible quantity of land in cotton to a given force. Now, a planter in Alabama, Dr. Cloud, acting on an opposite system, has endeavored to obtain from the smallest space the greatest product. The result of his experiment, the past season, 5989 pounds to the acre, is truly astounding, and being accomplished on land of inferior quality, originally of pine and black-jack growth, is the more so. From his statement, published in the Albany Cultivator, and copied into many other agricultural periodicals, it would seem that his system of planting and cultivation will ensure a product of near four bales to the acre; and although this may seem incredible, other experiments, on a smaller scale, it is said, have demonstrated that nearly double that quantity may be produced. A detail of the whole process, and mode of operation, by which this is effected, would doubtless possess more value than any thing I can say, did my space allow of it. It must suffice to state, that it proposes to restrict the cultivation of cotton to three or four acres to the hand, which will be sufficient to keep pace with the consumption, and to supply the demand, and at the same time greatly reduce the proportion of the inferior article, and to effect this at one-third of the cost, or the capital engaged in its production. The system favors the natural arborescent growth of the plant, and a more perfect development of its staple, which will greatly influence its market value. At a period like the present, when the production of cotton is so redundant, the price so depressed, the character and quality of the staple so greatly impaired, the system pursued by Dr. Cloud commends itself to adoptation with irresistible force. If we look forward to the future, what prospect of remuneration greets the cotton planter.

Admitting the East India experiment to be a failure, that no fear of successful competition exists in that quarter, still we see in the assurance of an increased production of our staple at home, fearful indications of a continued, if not a further depression of its value. View the active and earnest preparations making everywhere, to make good in the coming crop, by quantity, the reduction of price. See the wide alluvial plains on our borders, to what extent they have been reclaimed and brought into cultivation within the past year. Look at the middle and northern portions of our State, last year cheerless, desolate and abandoned, now filled by emigration—scarcely a plantation untenanted; all—all intent on cotton. Happily, we have learned wisdom enough in our adversity, to provide at home many of the necessaries of life; but the extent to which we are still dependant on foreign supply, in the circumstances of the country, is appalling.

The cost of horses and mules, farming implements, bagging and rope, pork and clothing, still required, forms a most formidable aggregate drained from our resources. It may be said that those articles are now cheap; yet do they not bear the same proportion as formerly, to our means of purchasing, or the value of our staple? Surely, it is time to seek out other sources of wealth, and new objects of industry.—Fortunately, few countries are more favored in this respect than ours, in its adaptation of soil and climate, to the production of many articles for which we have an ample demand at home. In the rearing of horses and mules, the growing of wool, the cultivation of silk, rice, indigo and tobacco, we have a choice of remunerating and profitable products, to divide our attention, with the production of our present staple.

The rice planters of the Carolinas and Georgia, are now accounted the most prosperous agriculturalists in the Union, and though this product may not be generally suited to our uplands, still we possess extensive tracts well adapted to its growth.

Silks, to the value of twenty millions, are annually imported into the United States. England imports nearly that amount of the raw material, and our own country is infinitely better adapted to its production than France, from which much of it is derived. It would prove the lightest and most lucrative employment we could adopt.

Sheep husbandry is rapidly increasing, and will soon form an important branch of industry. Tobacco and indigo, once the staples of the country, could be advantageously raised. Recent discoveries and improvements remove the objection to the latter, since the disagreeable and unwholesome process of manufacturing it is rendered unnecessary, a sufficient demand existing for the plant in its dried or cured state.

Many successful experiments have been made in the State of New York, and other sections of the country, in making sugar and syrup from the stalk of the Indian corn. It is better adapted to this purpose than the maple or beet, and it is thought, when the process is perfected, will not prove inferior to the cane itself.

With such resources, need the planter despond? Combining within the scope of his operations so many elements of independence, the exercise of prudence, industry and economy are only necessary to insure competence and prosperity. * * * * *

Though peculiarly suited to the care and nur-

ture of woman, she is not alone in her admiration of flowers.

Man, in the rudeness of his nature, may indeed deny the soft impeachment; and, "as outward life requires them not, ask wherefore were they made?" Yet, disguise it as he may, with the gentle Mary Howitt, his heart responds—

"To minister delight to man,
To beautify the earth."

It is useless to deny it, those fragile and fragrant gifts, so delicate in texture and beautiful in form, so exquisite in bloom and enchanting in sweetness, are too intimately associated with the purity and loveliness of woman, not to attract our regard, and command our admiration.

In all ages, and in all countries, where man has advanced beyond the savage state the beautiful gifts of Flora will be admired, preserved and cherished; and oft-times, with a yet holier and deeper feeling, will be reverenced as the smiles which Deity sheds on earth. Permit me, my fair auditors, to thank you, in behalf of the Society, for your attendance, and the interest you manifest in our success. Cheered and encouraged by your approbation and presence, our Fair becomes truly the Planters' Jubilee—a pleasant reunion of friends. On a former occasion, the conviction was expressed, that to your countenance and encouragement the prosperity of the Society was in a great degree to be attributed, and I now earnestly invoke a continuance of that interest, that active participation on your part in our operations, which cannot fail to add to the respectability and influence of the Society, and to insure its perpetuity.

Within the sphere of your household duties, many objects may be found, highly suited to exhibition and encouragement. The golden produce of the dairy—the fruits of horticultural skill—the useful web, and the finer tissues of the loom—the various articles fashioned by the needle, whether adapted to useful and economical purposes, or the more curiously wrought and tastefully executed objects of female ingenuity, need only be seen, to be approved, admired and emulated.

Coming from your hands, or as the result of your superintending and directing care, these will ever form the chief attractions at our Fairs, and whilst they claim our approval and admiration, we shall be stimulated in our appropriate departments to emulate your industry and endeavor to attain your skill. * * *

Southern Sportsman.

RECIPES.

To make good Hop Yeast.—To two quarts of water add a single handful of hops and three good sized potatoes, pared and sliced. Boil all together till the potatoes are done; strain the liquor on about one quart of flour; mash your potatoes and stir them in. When sufficiently cool, add not less than half a pint of yeast; let it rise and then set it away in a cool place, but do not let it freeze.

Graham Bread.—Take unbolted flour and pour on your wetting scalding hot; let it cool till about lukewarm, then add yeast enough to raise it. Knead and bake it as other bread.

Common Tea Cakes.—Take 3 cups of buttermilk, 1 teaspoonful pearlash and 1 cup shortening; roll and cut to suit your taste, and bake quick.

Yankee Pie.—Make cake as above; roll it into cakes the size of a common baking tin; when done, take off the top of the cake, and spread on apple sauce, sugar and butter; replace the top and it is ready for the table.

Johnny Cake.—Take 2 cups of milk, 1 teaspoonful of saleratus, 1 tablespoonful of butter, 1 do. of molasses; stir it thick with Indian meal, or one fourth flour and the rest Indian meal. Bake one hour.

Cough in Horses.—The boughs of cedar have been used with complete success. They should be cut fine and mixed with the grain.

LIME AS A MANURE.

I was a few days ago engaged in reading an agricultural periodical of some celebrity, and was rather surprised at the great variety of opinions made public through its pages, on the subject of lime as a manure. I have for some years believed that its action is as I shall hereafter describe it; and whilst I offer no objection to the views of others, and do not propose to enter into any controversy in favor of my own, I indulge a hope that when I add another to the numerous opinions on the subject, it will not be found to be the least worthy of belief, or most at variance with practical results.

It is understood to be one of the laws of nature, that when the principle of life has ceased to exist in organized matter, animal or vegetable, chemical action, till then suspended by the power of life, resumes its sway, the various parts of the organized lifeless body, are acted upon by light, heat, air and moisture; decomposition takes place, and a large part of the substance in various combinations, passes into the air in the gaseous form—of the carbon so passing off, either as carbonic acid gas, or carburetted hydrogen, the atmosphere becomes the receptacle weere it remains in a state of mixture, the carbon in the state of carbonic acid gas, which, although specifically heavier than atmospheric air, and in a state of mixture only, and not of chemical combination, is found generally diffused in all situations, and varying less from a constant quantity than might be expected.

When we remember that of animal and vegetable bodies, the largest constituent part is carbon, and that therefore new bodies depend upon carbonaceous matter for their growth and composition, it will be obvious that if the carbon in the atmosphere can be rendered available for the sustenance of living vegetables, by any process that we can make use of for that purpose, that then the most important operation in farming will have been performed.

I here premise, that the farmer does not make the crop to grow: he destroys the weeds, opens the ground to the proper depth, sows good seed in proper quantity and at the right season, covers it sufficiently—mixes with the soil such substances as are necessary for the growth of the plant, and in such place that the living plant can render them available to its growth; the laws originally impressed upon matter, and the blessing of Heaven produce the result.

Lime and magnesia were formerly considered as alkaline earths, and as such I shall here treat them; both of them have so much affinity for acids, that in nature I believe they are always found combined with them; my recollection is, that of the principal acids, both lime and magnesia have the least affinity for carbonic, and the greatest for sulphuric acid; yet as the stronger acids are not found in the atmosphere, whilst the carbonic acid is always there present—both lime and magnesia, when freshly calcined and in the states known as quick lime and pure magnesia, and exposed to the air, absorb carbonic acid gas from the atmosphere and become carbonates.

Thus far there appears to be an approach to general agreement, viz: 1. That vegetable and animal matter are formed in part of carbon: 2. That in the decomposition of vegetable matters, the carbon in part escapes into the atmosphere, combined with oxygen, forming carbonic acid gas: 3. That lime and magnesia, when in a caustic state, as produced by calcination, and exposed to the air, absorb the carbonic acid gas. Therefore, when lime or magnesia in the caustic state is reduced to an impalpable powder, and thinly spread upon the surface of the earth, it will rapidly become a carbonate; and thus we shall have a carbonaceous compound upon the surface of the earth, in such a situation as to be accessible to the roots of plants. I believe that many plants have the power of separating the carbon of the carbonates of lime and magnesia, thus placed within their reach, and appropriating it to their own growth and increase; but the progress of the growth and development of plants being under the government of the occult principle of life, our evidences can consist only of analogies—of probabilities drawn from the known properties of chemical substances.

Can the roots of plants absorb carbon from the carbonate of lime in the earth?

Certain plants do take up substances more difficult of solution, and for which I know not that any plausible theory has been offered: thus, pure flint is found in the cuticle of some plants: in the scouring rush, *equisetum hyemale*, and pigeon weed, *lithospermum arvense*, plants of our district, it is abundantly perceptible.

The following paragraph is extracted from the North American Review, for October, 1842, stating a case wherein the roots of living plants overcame an existing combination much greater than the case in question.

"It must have been in the observation of many persons who cultivate ornamental bulbous roots in glasses, that the inner surface of the glass loses its polish and becomes rough; this is merely from the decomposition of the glass—now water alone will produce no such effect upon glass; the living plant communicates by its roots through the water, (for the roots are generally not in contact with the glass) an influence powerful enough to separate the potash of the glass from its strong combination, and transfer it to itself. With the knowledge of such facts in our view, we are not left to the necessity of rejecting a belief in the existence of any process in vegetable life, merely because it cannot be explained by the laws of inorganic chemistry."

I make the following extracts from Liebig's Agricultural Chemistry, New World edition, 1843, page 9, on the article Humus:

"Woody fibre in a state of decay, is the substance called *humus*." "The carbonic acid which protects the undecayed humus from further change, is absorbed and taken away *by the fine fibres of the roots and by the roots themselves*, this is replaced by atmospheric air, by which process decay is renewed and a fresh portion of carbonic acid formed." "The roots perform the functions of the leaves from the first moment of their formation; they extract from the soil their proper nutriment, namely, the carbonic acid generated by the humus."

How will this theory be sustained by the results, so far as we have had experience?

If this be the true theory, lime should be spread upon the surface in the state of a fine powder, and suffered to lay upon the surface until it became mild by the absorption of carbonic acid gas—for the object is to obtan the carbonic acid to unite with the lime, *from the air and not from the earth;* for if the lime is placed in a situation to obtain carbonic acid from the earth or the decaying humus of the soil, no advantage would be gained; it being very probable that living plants can assimilate the carbonic acid more easily from decaying humus, than from carbonate of lime—but if the lime absorbs the carbonic acid from the air, it is a quantity fixed in the soil in addition to what before existed there, as manure, decayed humus, &c. So far as we have experience, it is, I believe, decidedly in confirmation of the theory. I applied lime to my grounds many years ago, putting it on at the same time with the stable manure to the wheat crop, and with some care to have them ploughed in together, without exposure to rain or dew; the results were so discouraging, that I discontinued the use of lime for some years—the wheat crop was generally injured, although good crops of grass succeeded, which should have been the result according to the theory—the carbonic acid gas, given out by the decomposing manure, instead of being made available to the growth of the wheat, became absorbed by the lime, thus diminishing the proper support of the wheat, but which was afterward furnished to the grass. Thirty or forty years ago, when little lime was used as a manure, it was occasionally mixed in the dung hill; but more frequently mixed with corn stalks and decaying

vegetable matter, as a kind of compost; these methods of using it have been abandoned, as improper; which should be the result according to the theory.

According to this theory, there should be no disadvantage from using lime, (so called) much mixed with magnesia, as the latter requires about as much carbonic acid for its saturation as the former; it is more soluble, and in particular, is more acted upon by ammonia, but requires more time for its saturation with carbonic acid gass; it would therefore require some longer time than pure lime, before being ploughed down.

From recently published analyses, it appears that the lime of the great valley, or range, passing through Montgomery, Chester, Lancaster and York, is nearly one half magnesia. Of this lime, millions of bushels are annually sold as a manure, and used in Jersey, Pennsylvania, Delaware and Maryland, with results so encouraging, that the demand has increased more than ten-fold, within ten years.

From the circumstance that lime is found in small quantities in some vegetables, it has been supposed that it is useful only for the purpose of furnishing the requisite quantity of lime thus found in their substance; late experiments made by incinerating vegetable matters, go to show that 50 bushels of lime per acre, would not be taken up in an hundred years, by those plants in which it is found to exist in the largest proportion.

It may properly be objected, that if the roots of plants can and do decompose the carbonate of lime in the soil, and use the carbon or carbonic acid gas, for their own growth and nourishment, that the lime would again be caustic and uncombined. It is, however, a possible case, that plants may possess that power, and that they may not always be obliged to use it: it is known that in dark cellars and covered places open to air, but not to light, that nitrates are formed; and in whatever way any acids may be formed in the earth, having more affinity for lime than the carbonic, the latter would be ejected from its combination with the lime, which would unite with the stronger acid, (if the nitric, forming a soluble compound and sinking away in the earth,) in which case the carbonic acid gas would be uncombined, and as available for the growth of plants, as if arising from the decomposition of stable manure.

To conclude, my view is, that the air as well as the soil contains the elements of which vegetable matters are in part formed; that the living plant appropriates those elements to the purposes of its own growth and nourishment, by its roots from the soil, and by its leaves from the air—that the *air* always contains a sufficiency of carbonic acid gas; but that the *soil* does not, and that we spread lime upon the soil to absorb the carbonic acid gas from the air, to add it to the soil.

A. W. CORSON.

Farmers' Cabinet.

SOWING CORN.

Messrs. Editors—As the sowing of corn has attracted the attention of some of our farmers, I will relate a small experiment made by me last season, that others may shun the errors I fell into for want of experience.

I appropriated a small piece of land (3-16ths of an acre,) to that purpose. The land was in corn the year before, producing about forty bushels to the acre: the hills were split, three loads of yard manure spread, harrowed and plowed under, say from 5 to 6 inches deep, harrowed again, and the corn sown at the rate of four bushels to the acre, of the early twelve-rowed yellow corn, small kernel, buried with light horse plow, and rolled.

The corn was sown on the 10th of May, the ground light and in fine order, but cold rains soon came on, and all know what an unfavorable season we had for corn; it was twice nipped by frost—the last time on the 11th of June, this gave all the weeds a chance to grow, and contest the ground with the corn; and although the ground was well tilled the previous year, and no weeds permitted to seed; yet there were enough to injure the crop, although the corn out topped them in the end. When the corn was fully in tassel, it was cut with the cradle, laid in swath, turned to facilitate the drying. When well wilted it was bound in small bundles, stooked and capped with the same; when cured, a part was weighed before carrying in, and by computation found the yield to be 5¾ tons per acre. It was fed mostly to sheep and calves, but all kinds of stock eat it with avidity. Probably there is no vegetable we raise for stock, that contains more saccharine matter than corn, and it appears the sowing of it may be made profitable, especially to those who occupy but little land, whether it be wanted for soiling or winter fodder.

The most essential errors I fell into were, first, I sowed too much seed. Three bushels of the small kernel corn I believe better than four, as mine was so thick it did not tassel. In the next place, I sowed too early by about three weeks. We can have but one crop in a season in this northern climate, and the summer months are sufficiently long to bring corn into tassel. I think, therefore, the fore part of June will be in season for sowing for winter fodder. No one need be told that land for corn must be rich, and for a sown crop should be free from weeds. If the sowing be put off until June, many weeds may be destroyed by plowing or otherwise stirring the ground before sowing. The curing must be attended to, as on this the value of the crop is mostly depending; and to make more sure, I would recommend whenever it is housed, to set the bundles in an upright position, and not pack them away as we usually do grain.

Yours, respectfully,

B. BLACKMAN.

Verona, N. Y., April, 1843.

Central New York Farmer.

LICE ON ANIMALS.

If you have purchased any animals that were poor, or if you have most unwisely allowed any of your own to become so, now is the time to examine all such carefully, and see that in addition to their being poor, they do not become lousy. There is not an animal that does not, under suitable circumstances, nourish in its hair, wool, feathers, or its skin, some kind of louse; and sometimes more than one kind of these parasites lodge and prey on the same animal. In ordinary cases, they do not produce much mischief, but when they increase so much as to produce the disease called Phthiriasis, they become truly formidable. The cause of animals being troubled with lice, may usually be traced to a want of cleanliness. When the dust and sweat accumulate on the hair, and in contact with the skin of the ox or horse, are allowed to remain undisturbed by the comb or brush; when the stables are kept filthy, unventilated, and unwholesome: when animals, reduced in autumn by want of pasture, or by living in unhealthy ones, are suffered to take their chance for the winter without extra care or attention; or when a beast loaded with pediculi, is turned into the yards or the stables of those exempt from these parasites, it may be expected that they will multiply and infest animals.—When we see horses rubbing their tails, biting their manes, and showing other signs of uneasiness and irritation; when cattle are observed to be rubbing their heads against posts of fences, and the hair coming off from the head and neck; or when sheep tear out tufts of wool with their teeth, and bite these places till blood appears, we may expect that lice are present. On most animals, these parasites have some favorite place of resort; on horses the main and tail; on horned cattle, around the nose, base of the horns, and the neck; on sheep, they run over every part; and on swine they do not seem to be confined to any particular location.

Pure air, room for exercise, plenty of food, and above all, cleanliness, are the first things to be attended to in the cure of this evil. Currying, brushing and washing should be resorted to, as, except in bad cases, this treatment will be usually sufficient to free the animal from these insects, without recourse to other remedies.—When these fail it will be necessary to have recourse to such external or internal applications as shall operate directly on the vermin.

One of the most common remedies is the mercurial ointment, unguenium; but this, though effectual, cannot be used without some danger, as numerous instances have occurred in which valuable animals have been destroyed by its use. When its use is necessary, care should be taken to prevent the animal from biting itself where the ointment is applied, until it has had time to take effect. A decoction of tobacco leaves, in a strong lye, forms a very good wash; but this, too, owing to the narcotic poison of the tobacco, has caused death. Various vegetable remedies have been resorted to, among which are the seeds of the Delphinium staphysagria; and the leaves and flowers of the Ledum palustre, or marsh tea. The roots of the black hellebore, or a decoction made from them, have been used with success; and it is said the water in which the skins or parings of potatoes have been boiled, will effectually destroy lice by a few washings. The internal use of sulphur is an excellent remedy, and if given to animals occasionally, is one of the best preventives.

It is more difficult to apply remedies for lice to sheep, than to any other animals. The English shepherds make use of a salve compounded of white arsenic and corrosive sublimate, carefully parting the wool, and applying the ointments in small quantities directly to the skin, and rubbing it down with the finger. Tessier prefers tobacco smoke to this ointment, as involving less danger in its use. The sheep is held in such a manner that tobacco smoke is forced from a bellows among the wool to the skin in all directions. After this fumigation, the sheep must be placed in the open air, that the vapor may have room to pass off without being inhaled by them. Perhaps the best remedy for lice in animals, where they have not become so numerous as to produce the disease phthiriasis, is to rub any oil, such as whale oil or melted lard, on such places as they most frequent, or on parts of the animal where they will be most likely to come in contact with it. All the pediculi breathe through what are termed spiracles or openings in their bodies, and the least particle of oil spread over their bodies, by causing suffocation, at once effects their destruction. This is also a perfectly harmless remedy. But prevention in this case is better than cure; and neatness, cleanliness and good keeping, by insuring comfort and health, leaves no opportunity for the attacks of vermin.

Albany Cultivator.

Facts Worthy of Notice.—Whenever the farmer or planter discovers his field covered with sheep sorrel, he may conclude that the soil needs liming, the presence of the sorrel being unerring evidence of the absence of calcareous matter, and that the soil is too acid for the purposes of healthful vegetation.

Lands, too, whose natural growth is pine, require lime, as that wood almost always delights in an acid soil devoid of lime.

Clover, sainfoin, lucern, and all grasses of this family, require that there should be lime in the soil on which they may be grown, and, indeed, it may be said to be labor lost to attempt to cultivate them advantageously on lands in which this mineral does not form a constituent element. Now, may it not be the absence of lime in much of the soil of some of the southern portions of our country, which opposes such obstacles to the growth of clover? We think it demonstrable that it is, and we are equally certain, that if lime or marl were applied to all such lands, that clover might be grown there as well as in any other part of the country.—*American Farmer.*

Educate a community in the idea that to work with their hands is degrading and dishonorable, and you educate them for vice and misery.

WEDNESDAY, JUNE 7, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

OUR ACKNOWLEDGEMENT.

To our friends in various sections of GEORGIA, SOUTH CAROLINA, ALABAMA, MISSISSIPPI and TENNESSEE, who have interested themselves in extending the circulation of the *Cultivator*, we beg to return out most sincere and cordial thanks, and to assure them that the work is daily receiving a degree of favor for which we did not dare to hope. We trust however they will not relax their exertions until it is placed upon a most secure and stable foundation, which it is rapidly acquiring.

CURING SWEET POTATOES.

In this number of the *Cultivator* we present the reader with two communications on the subject of curing this valuable esculent, for which we thank our friends "COPELAND" and "AGRICOLA, JR.," and hope they will continue to enrich our columns with their views on any subject calculated to interest and instruct the planter.

To the enquiry of "AGRICOLA, JR.," we have to remark, that at present we are unable to give him the best and simplest mode of analysing soils, but as soon as we can procure from one who has much experience on this subject the best mode, we shall communicate it through our columns.

☞We have been furnished by our friend, B. H. WARREN of this place, with the following list of the yield of wool as taken from ten (half blood) *Leicester* sheep, this spring, and which were last spring lambs:

No.	1,	6¾ pounds.
No.	2,	6½ "
No.	3,	6 "
No.	4,	5¾ "
No.	5,	5¾ "
No.	6,	5½ "
No.	7,	5 "
No.	8,	4¾ "
No.	9,	4¾ "
No.	10,	4½ "
		55

Making an average of 5½ lbs. of wool to each sheep.

The above yield is certainly a very fine one for this section of country; and we should like to see many more of our planters turning their attention to this stock.

These sheep are spoken of in the highest terms by those who have seen them, as being large, well formed, clean limbed, and easy to fatten, and their yield of wool is certainly very good. And it is further to be remarked, as we are informed by Mr. W., that they have not been fed but once during the whole of the past winter, which was during the snow in March. Having been put on a rye lot the first of November, they have done well and kept fine on rye the whole time, and even to this date.

AGRICULTURAL WORKS.

"THE AMERICAN AGRICULTURIST" is the title of a most valuable and interesting publication, issued monthly in New York, edited by A. B. ALLEN, Jr., and, as its name imports, is devoted to American agriculture. The work is rapidly acquiring a large list of valuable correspondents throughout the Union, and bids fair to be a work of no ordinary merits in its department. The typography is unexceptionable.

FARMER'S ENCYCLOPEDIA.—No. 6 of this valuable dictionary of rural affairs, is on our table. We have before alluded in terms of commendation to this excellent work, and we need now only repeat that it should be in the hands of every planter.

CURE FOR WORMS IN CHILDREN.—A writer in the Farmers' Register, who being a slaveholder has a large family under his care, says that for nearly thirty years he has found the following preparation a certain cure for worms: "Take the fat of old bacon, sliced and fried in a pan until the essence is all out of it, take out the rind first, then put in as much wormseed (vulgarly called Jerusalem oak,) as is necessary, as much sugar or molasses as will make it palatable, and give it three mornings in succession.—The children will eat it freely—some you will have to restrain from eating too much. Incredible as it may appear, I have known as many as one hundred and twenty or thirty large worms come from a child three or four years old. I usually give the medicine spring and fall."

INDUSTRY.—Every young man should remember that the world always has and always will honor industry. The vulgar and useless idler whose energies of mind and body are rusting for want of exercise—the mistaken being who pursues amusement as a relief to his enervated muscles, or engages in exercises that produce no useful end, may look with scorn on the smutty laborer engaged in his toil. But his scorn is praise. His contempt is an honor. Honest industry will secure the respect of the wise and good among men, and yield the rich fruit of an easy conscience, and give that hearty self respect which is above all price.

Toil on, then, young men. Be diligent in business, improve the heart and the mind, and you will find the well-spring of enjoyment in your own souls, and secure the confidence and respect of all those whose respect is worth an effort to obtain.

INDELIBLE INK FOR LINEN, &c.—Put half a drachm of lunar caustic, (nitrate of silver,) into a small vial of water: add a piece of Gum Arabic of the size of a pea, and a little of the paint called sap green, to make it more legible while writing. When the whole is dissolved, it is fit for use. The part of the cloth to be written on must be previously wet with a mixture of a small quantity of saleratus and gum Arabic, dissolved in water, and pressed smooth with a hot iron. The writing should be exposed to the sun, which will cause it to dry darker than in the shade.

DISEASE OF COWS.

Messrs. EDITORS—A friend of mine lately lost a very valuable cow, soon after calving, under the following circumstances. She calved and did well to all appearance at first, but soon began to be affected in her fore quarters; if she attempted to walk, her fore feet remained stationary, while her hind ones moved around circularly. She soon died. She had been kept well for three or four years, and was so fat, that when she died 100 lbs. of tallow were taken from her. As it is an uncommon case among us, permit me to inquire of you, or some of your numerous subscribers, the nature of the disease, the remedy, &c. S. W. BARTLETT.

Scantick Village, Ct.

The case noticed by our correspondent is one of *puerperal fever*, or as it is termed by veterinarians, "*dropping after calving*." Cows in high condition are most subject to this disease, which usually appears in from one to five days after calving. The first symptoms are decidedly febrile; the animal is restless, shifting her feet and breathing laboriously. The nose is hot, and the udder is inflamed, enlarged, and tender, from the very commencement.

REMEDY.

Bleeding, from six to ten quarts, to be regulated by the impression made on the circulation, must be resorted to at once, and the bleeding must be followed by physic, for which purpose a pound or a pound and a half of Epsom salts are best, and half pound doses every six hours, till the bowels are opened. If the disease is not attended to in the outset, and it is too frequently neglected, the nervous system is speedily attacked, when the symptoms of staggering, &c., noticed by our correspondent, usually occur. It is occasioned by a partial paralysis of the fore or hind quarters, most commonly the last; the animal soon falls, her head is bent back to her sides, and death soon supervenes. In the last stages, there is little hope or chance of relief; but if the pulse is such as to indicate fever, bleeding may be resorted to till the last, with a bare possibility of saving the animal; but great care is requisite, as the bleeding, carried too far, is fatal at once. In some papers in the Veterinarian, Mr. Field relates several instances successfully treated by Epsom salts in large quantities, followed immediately by Croton seed and sulphur.—*Albany Cultivator.*

ENGLISH AGRICULTURE.

Whatever opinion we may form of Britain, her pride, arrogance, insolence, presumption, vanity—faults, too, that will have to be amended within ten years by the compulsory process of a general alliance of nations against her—yet we must all confess that her agriculture is the most stupendous thing under heaven! When it is remembered that the crop of turneps grown in Norfolk alone is greater than the value of her trade with China; that the market price of geese brought from the Lincolnshire fens is more than her trade with Denmark; that you shall see, as a common thing, a hundred acres of turneps, or a hundred acres of beans, or thirty acres of cabbage in a single field—a farm of three hundred acres all mown, or a farm of the same size, (three hundred acres) all in crops—the live stock on a single farm worth $50,000—twenty horses employed on one farm every working day in the year, and by means of thrice ploughing, (heavy clays,) turning nine hundred acres in a single year—I say, when this is remembered, it will be seen that "great" as Britain is in every thing, the superlative degree of greatness is in her agriculture—in her soil, naturally poor, but made rich by the application of capital and unwearied assiduity, good sense and enterprise. While in this country we fail most from the want of capital, and from the circumstance that agriculture does not rank as an employment with others (especially with trade it is not valued) as it ought to be. The English contend that it was never so valued in a democratic country; agriculture being, in their estimation, substantially an aristocratic employment; and it must be con-

lessed that this is true of England. To be wanting in the dignity conferred by landed possessions, is to want that which conducts to the highest offices and the most exclusive society.—The term country gentleman, is in England almost an actual patent of precedence; and so far do they carry this, that no man in trade can marry into a family of landed descent and possessions, unless he add to wealth an eminent character for talent.—*Farmers' Monthly Visitor.*

There is nothing in a democratic government that deters from the pursuit of agriculture.—There is no portion of the earth more zealously devoted to our democratic institutions than the people of Virginia, yet are they strictly an agricultural population. In truth, wherever nature has granted a favorable climate and soil, such are the innumerable advantages of this delightful occupation, that it must enlist amongst its votaries the great mass of mankind. Those, whose means induce them to look rather for enjoyment than accumulation, will always seek the noble pleasures of a country life; and he who wishes to engage in agriculture where it is sanctioned by the example of the aristocracy of wealth and learning, need not go to England to seek it. He will find it throughout the whole southern country. The farmers compose the aristocracy of Virginia, certainly; they know and feel it; you can see it in the slow and solemn gravity with which they pace our streets, when business brings them to the city; they look down upon the hurrying cit, as they meet him on the side walk, with ineffable contempt; they know that he is the patient drudge who labors in their service: whilst they, the lords of the land, revel in the luxury and ease that their more favorable occupation secures them. We know nothing here of that which is so often complained of at the North, the unjust degradation in which agriculture is held. The name of *Planter*, at the South, is almost equal to a patent of nobility, and the occupation, in point of dignity and importance, has nothing to fear, with us, from the sneers of the most haughty.

Southern Planter.

A PLEA FOR THE BIRDS.

As the season is at hand when the birds begin their labors in our fields and gardens, it becomes their friends to interpose for their protection from the wanton persecution which pursues them as regularly as they make their appearance. No fact in natural history is more certain than their really useful services—though we are not prepared to admit this to be their only or their highest claim to our regard. It has been ascertained by various and careful experiments that they protect our choicest fruits from the ravages of the insect tribes. That they are sometimes mischievous in the autumn is not denied, but the little harm they do in the fulness of the year is more than compensated by the destructive havoc they make amongst the insects and vermin of the spring. The quantity of grubs destroyed by crows, and of catterpillars and their grubs by the various small birds, is immense. Other tribes of birds, which feed on the wing, as swallows, martins, &c. destroy millions of winged insects, which would otherwise infest the air, and become insupportably troublesome. Even the titmouse and bulfinch, usually supposed to be so mischievous in gardens, have actually been proved only to destroy the buds which contain a destructive insect.—Ornithologists have of late determined these facts.

An English paper tells us that some of the large farmers in Devonshire, under a strong prejudice, determined a few summers ago, to try the result of offering a great reward for the heads of crows; but the issue proved destructive to the farms, for nearly the whole of the crops failed for three succeeding years, and they have since been forced to import birds to re-stock their farms, We add a few other facts collected from experience:

"Every crow requires at least one pound of food a week, and nine-tenths of their food consists of worms and insects; one hundred crows then in one season destroy four thousand seven hundred and eighty pounds of worms, insects and larvæ: from this fact some slight idea may be formed of the benefit of this much persecuted bird of the farmer."—*Mag. of Nat. History.*

The Blackbird destroys a great number of Grubs, &c.—"Last August I observed eight or ten Blackbirds busily engaged in the grass plain in front of my house, and the grass where they were seemed dying, as was hinted, from their mischievous operations, and the gun was suggested as the remedy. Suspecting the object of the birds' search, I turned up a piece of turf with the spade, and found it literally swarming with grubs of various sizes. I need not say that they were allowed to pursue their game undisturbed, and that the grass plat soon regained its verdure. This is another instance of the utility of preserving birds on farms, and in orchards and gardens."—*Ib.*

* * At the season to repay the gardner for the tithe of his crop, their natural due, they fail not to assist in ridding his trees of more deadly enemies which infest them, and the small caterpillars, beetles, and various insects now constitute their only food; and for hours at a time they may be seen feeding on the all dispoiling canker worm which infest our apple trees and elms."—*Nuttal's Ornithology.*

The Boblincoln is perhaps next to the Cedar bird or Canada Robin, the greatest destroyer of the canker worm. Building her nest and rearing her young under the apple trees, as this bird often does, she requires an immense number of worms for their subsistence just at the time that they are most destructive. "I have observed one of these birds," says a neighbor, "go round the limb of an apple tree in a spiral direction, and destroy in this way every worm on the tree, in an incredible short time. No man," added he, "can calculate the value of birds on a farm. I have no doubt but that they have saved me equal to the labor of one man for the season, besides preserving my trees from destruction."

Birds, then, not excepting the hawks and owls, are vastly more useful than injurious to man. None of them should, under any pretence, be destroyed.—*Sentinel of Freedom.*

Home and its Affections.—How sweet are the affections of kindness! How balmy the influence of that regard which dwells around our firesides! Distrust and doubt darken not the brightness of its purity; the cravings of interest and jealousy mar not the harmony of that scene. Parental kindness and filial affection blossom there, in all the freshness of an eternal spring. It matters not if the world is cold, if we can but turn to our dear circle, and ask and receive all that our own heart claims.

Horses.—An ounce of *prevention* is worth a pound of *cure*. Horses should never stand long on a dry plank floor. Their fore feet, particularly, should rest on something more pliable.—Some, who object to loam and to tan bark, keep a trough of water and require the horse to stand in it for hours. By traveling fast on hard roads a fever is created in the fore feet, and road horses are ten times more subject to it than farm horses. When a horse has travelled all day on a hard road, it is cruel to make him stand all night on a hard floor.

To Gardeners.—It you wish to preserve your cabbage from the ravages of the cut worm, hill up the plant until the bud is covered with earth a half an inch or an inch deep, which will not injure the plant. Be sure to let the main leaves stand up out of the ground. The worm will then cut off the stems of the leaves instead of cutting down the stalk, and the bud will soon grow out of the ground uninjured by the covering. This plan has been tried with success in this place, when every other effort to preserve the plants had failed.—*Dahlonega Times.*

Corn Stalk Syrup.—We have before us an article of Corn Stalk Syrup, which is equal, in every respect, to the best molasses. It was left at our office by Col. John S. Thomas, of this county. The process of manufacturing, we learn was of the simplest character. The corn stalks were cut up, beaten in a trough, and then thrown into a common cider press—the juices of the stalk then underwent boiling, &c., and the syrup is thus made. Our planters without exception, should prepare to make this syrup—if not for a market, at least for their own home consumption. The sample before us was made in South Carolina. The stalks from an acre of land, it is said, will produce about ninety gallons.—*Georgia Journal.*

AUGUSTA MARKET.

Tuesday p. m., June 5.

Cotton—The market for a few days past has been very firm and active, with heavy sales for the season, at prices ranging from 4¼ to 6¾ cts. as extremes of the market—principal sales 5½ to 6 cents. By yesterday evening's mail we had accounts from Liverpool to the 19th May, showing a shade advance in the lower and middling qualities, which will doubtless sustain the firmness which our market has exhibited for several days past, and may give it more activity with a very slight improvement in those descriptions.

Exchange—The rate of Exchange on the Northern and Eastern cities remains at par, and the supply is equal to the demand for business purposes. Central Bank notes range at about 15 ℔ cent discount. Alabama notes 15 @ 17 ℔ cent discount. State 6 ℔ Bonds command readily 55—there are however but few offering.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, invariably in advance. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

Advertisements pertaining to agriculture will be inserted for one dollar for every square of twelve lines, or less, for the first inscrtion, and seventy-five cents per square for each continu ance.

☞Post Masters are authorized to receive and forward money free of postage.

☞All communications must be post paid.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., JUNE 21, 1843. No. 13.

COMMUNICATIONS.

STANFORDSVILLE, PUTNAM CO., June 9th, 1843.

To the Editors of the Southern Cultivator:

DEAR SIRS—I see a piece in your paper of May 24th, headed "Anonymous Contributors." I agree with you on that subject, as I always take more interest in reading a communication with the writer's proper name under it, than I do those that have some fictitious name—particularly those that are written on the subject of agriculture and its kindred pursuits. But, sirs, there are a great many farmers that have but little education, though some of us may have as good ideas on practical farming, and as much experience in all its various branches, as those who have the advantage of education, and can write with ease all they know on the subject. I should, therefore, like to see a promise from you, that you will set in order all communications that are written for your paper on the subject of agriculture;—giving those that are inclined to write for your paper to understand that they need not fear to put their proper name to their communications. You will readily perceive that I am one of those that stand in need of your help in the correction of my errors, both of spelling and diction. Under these considerations I shall, at this time, give you a few passing thoughts, and shall confine myself within the range of the planting and farming interest, and term them

PRACTICAL HINTS.

In the first place, every planter should strive to make corn enough to serve him, and by no means undertake to make cotton to buy corn with, or any thing else that can be conveniently raised at home—especially while cotton is at its present low price.

No farmer or planter should undertake more than he can have done in its proper time, and that well done when it is done. This way of being under whip and spur the year round, for the sake of making a few more bales of cotton than could be made by taking things concerning our interest in their proper order, I think unwise, and could give several reasons, but one at present is enough. Such a planter never has any time for improvement, such as ditching his hill sides to prevent their washing off, nor for raising manure. He can scarcely find time to haul out and apply what little has accumulated about his stables, (if he has any.)

All farmers should keep their fencing in good order; see that the holes and water-gaps are well stopped. It is much easier to keep pigs, as well as every other kind of stock, out of the fields, than it is to stop them out after they have once found their way in and committed some depredations on the corn, potatoes, &c.

Every farmer should raise all the manure he can, and be sure to apply all he has at least once a year, and not suffer it to lie about his stable yard for two years, by which time about one half its fertilizing qualities have evaporated. My plan is to haul out and apply all I have in the spring, invariably broadcast, except cotton seed, which I apply to the hills of my corn. What manure I can scrape up in October, I have hauled out and scattered on the poorest parts of the field where I seed my wheat, and, from my experience, manure is as profitable used in this way as any other I have tried.—Strong land for wheat is better without manure than with it. The reasons why I might give, but believe it mill not be doubted by men of experience; but on poor land for wheat, manure shows its benefits to the last inch of its application, and if the manure be of a valuable kind it may be put on the land quite thinly, but never should be scattered on the land till every thing is ready to plow it in, as there is great loss by evaporation should it be long exposed to the air and sun.

We have seen accounts, in some of the agricultural papers, of large quantities of corn being raised per acre in some of the Northern and Northwestern States. Such statements may be doubted by some of my Southern friends for aught that I know. I have no just grounds to say that they are incorrect. But I can say to the planters of this State, that we need not calculate on making as much corn to the acre as is made to the West and North of us. I shall congratulate the man who can arrive at one half the quantity, or even to 60 or 70 bushels per acre. Do not be discouraged, however, by these views, but let us make all we can. My reasons for this opinion are, first, our soil is not near so deep as it is where those large crops of corn are made; and in this climate corn cannot bear being planted more than half as thick as where they plant for those large crops. How do you think corn would stand even a slight drought in this climate, and on our thin soil, if planted only about two and a half feet apart each way. I, for one, believe that it would not do; yet it is certain where those large crops are made that the corn is planted very close—in some instances nearer than above stated.

In conclusion, Messrs. Editors, I thank you for undertaking to publish a paper devoted exclusively to Southern agriculture. I wish you success in your laudable enterprise, and hope you will not lack for subscribers or contributors among our planters and farmers, which will render the Cultivator so interesting a paper that every man that runs as much as one plow will take it. For I concur with a writer for the Tennessee Agriculturist, who says, "that every farmer that runs as much as one plow ought to subscribe to an agricultural paper."

I am, sirs, yours respectfully, &c.

JOHN FARRAR.

MOUNT HOPE, EFFINGHAM CO., June 10, 1843.

Messrs. JONES—I see in your Cultivator, page 82, a very sensible letter from Mr. Ernest, of Bibb county, upon matters and things generally, but upon the subject of the silk business particularly. This part of his letter is particularly interesting to me, as I have been engaged in the culture of silk for several years in a small way. I fully concur with Mr. Ernest in the opinion that silk can be cultivated in Georgia as profitably as any where else, or as any thing else. I will not say it can be made as profitable as cotton ever was, but as profitable as cotton ever can be again.

Mr. Ernest thinks if there was a market for cocoons in his neighborhood, many poor persons would engage in the business, and one lady who had abandoned the business, had said to him, that she would resume it if she could get $2 a bushel for cocoons. I hope this market will not be long wanted; indeed, I will say it shall not be wanted at all at such prices, for I will give, in Macon, for all cocoons of good quality, $2 50 per bushel, and for the best peacocoons, $3 per bushel, and will establish an agency there for the purchase of all that may be offered, as soon as I am advised that they can be obtained. I am surprised that Mr. Ernest has not opened such a market at his own house before now; for if he can buy cocoons at such prices, he could surely make a profitable business of reeling and selling the raw silk, if he did not choose to manufacture it. I have obtained a machine and manufacture all I make into sewing silk. I have found some difficulty in dying the various colors without destroying or injuring the lustre, particularly the black and blue black.

I send you herewith seven skeins of as many colors, from which I think you will conclude I have succeeded tolerably well in giving the colors and retaining the lustre.

The greatest difficulty I find in the business is to preserve the eggs for a succession of crops. I have succeeded very well with the second crop, but I find so much difficulty in preserving

them longer, that I now obtain eggs from the North for my third and fourth feeding; but I hope we shall yet be able to overcome this difficulty. The early part of this season was cold, wet and unfavorable, yet my worms have never been more healthy, or made better cocoons. My second lot are just beginning to spin, and my third are hatched and ready to take their places. Respectfully yours, &c.

HUGH CASSIDEY.

CRACKER'S NECK, June 12, 1843.

Messrs. JONES—Having given the weight of my small influence towards the circulation of the Cultivator, and believing that any idea, however humble, that is profitable, will receive a welcome from the friends of agriculture and rural economy, I drop you a few lines relative to my mode of attending to cattle, especially milch cows, and I have found it so cheap and profitable that I cannot consistently withhold it from your numerous readers.

My mode is to build a common shed or shelter, having the roof to turn either way from the centre—to effect which, I place my centre posts say 14 feet high, and my eave posts say 7 feet high. From the centre to the side post there is a space of some 7 feet. I then put up what I term my ridge and eave poles, and nail on my rafters and cover in with four foot boards. I then have large troughs and place them through the centre of my shed, and fit it out in stalls some five feet wide, and place a rack immediately over the troughs to hold the provender. I have a small lot attached, which I keep well littered, and from which I make an immense quantity of first rate manure. I use the leaves of the woods for my litter, and when I find they are sufficiently decomposed to make a good manure, I pile them up and haul in more, by which means I find no difficulty in keeping on hand a good supply of first rate manure. I always keep plenty of salt in my troughs, and I find cattle do much better than to salt occasionally, as the cows do not overcharge their stomachs, and the consequence is they keep in a healthy condition and give us any quantity of rich milk and yellow butter. If you think the above worthy a place in the Southern Cultivator, it is at your service.

Respectfully, C. S. C.

CATTLE AND SHEEP OF GREAT BRITAIN.—We find the following in a late English journal, and give it for the purpose of comparing it with some of our own statistics and prices:

"The total number of horned cattle in the United Kingdom is estimated at 7,000,000, and the total number of sheep at 32,000,000. Valuing the first, per head, at £10, and the last at 25s., both together will give a total value of £110,000,000.

In the United States, according to the census of 1839, the number of horned cattle was 15,000,000, and the number of sheep 20,000,000.—But the difference in the estimated value is the most striking point in the comparison. There the average value is put at about $45 for the cattle, and about $6 for the sheep. Here, an average price of $12 for the cattle, and $1 50 for the sheep, must be considered a liberal estimate. This fact shows why the prices of meat are so high in Great Britain, and proves that we ought to be able to furnish them a supply of beef at remunerating prices. We think it clear that in the present position of trade, tariffs and prices, a fair export trade in beef and pork to England may be expected.—*Albany Cult.*

ASHES.

To the Editor of the Farmers' Monthly Visiter:

Mr. HILL—I have read in several of the agricultural papers, within a few months past, various accounts of the value of ashes in agriculture, both leached and unleached; and in most cases their application was attended with decidedly beneficial results. But there is a great difference in the value of soapers' leached ashes and those from the pot or pearl ash factory. Dr. Dana says, "the soap chandler, in leaching ashes, uses about one peck of lime to each bushel of ashes." This is used for the purpose of taking up the carbonic acid in the ashes, which makes the ley *caustic;* it then readily combines with the oil or grease, and forms soap. The lime used with the ashes is "quick lime," or in other words lime that has had its carbonic acid driven off by the process of burning. After being leached it is carbonate of lime, from the carbonic acid derived from the ashes, and is chemically the same as before being burnt. Then in 125 bushels from the soap boilers, we get 100 bushels of leached ashes, and 25 bushels of carbonate of lime. The manufacturer of pot or pearl ash, covers the bottom of his leach tubs with swingle tow or straw, and puts over it a bushel or two of slacked lime, and does not renew the lime again during the season of making; consequently, there is no lime mixed with the leached ashes from the potash.

From the above facts, every one will see there is a material difference in the value and effects of the two kinds. Therefore, the farmer that uses leached ashes from the potash, expecting to realize the same results as those do that make use of soaper's ashes, will be likely to meet with disappointment. I have never seen Dr. Dana's "Muck Manual," but have read a few extracts as published in the agricultural papers. In one of them, the Doctor goes into a calculation to prove that soils are not exhausted of their lime and ashes by cropping or cultivation. For by his figures he makes out that an acre of soil to the depth of six inches "contains 3,626 lbs. of lime, and 73,311 lbs. of potash, or nearly 1¼ ton of lime, and 36 tons of potash." Well, every farmer must say there is enough in all conscience of lime and potash in his soil; and I do not at all dispute the Doctor, but if there is that amount I believe it is nearly insoluble, and therefore of little use. Liebig says, the lands in Virginia, by long cultivation, become entirely unproductive in wheat, for *want* of potash in the soil; he says, (if I recollect right, it being more than a year since I have seen his book,) that there is twelve pounds of potash annually carried off the soil, in the grain and straw of an acre of wheat—1200 lbs. in a hundred years. But according to Dr. Dana's statement, there would be left *there*, in the soil, some 36 tons of potash per acre. Now, Mr. Editor, I am a "plain, practical, every-day farmer, and shall not attempt to decide where learned doctors disagree. But being willing to contribute my mite for the benefit of our *craft*, I will state a few facts, and give my views, with the hope that they may result in further investigations, but not having the happy talent of saying much in a *few words*, I hope you and your readers will excuse the long yarn I am about spinning.

I think I can furnish a few facts, to prove that the application of ashes to the soil in addition to the 36 tons, is attended with beneficial results. I believe also the part that ashes perform in agriculture, is not fully understood. The general opinion is, that it acts as a stimulant to the growing plants, and a decomposer to vegetable matter in the soil, and perhaps the above opinion is partially correct. I apprehend the most important part ashes perform in agriculture, is in decomposing *silicia*, and rendering it soluble, so as to be taken up by the rootlets of plants, and by proper vessels carried to every part, and there assimilated and applied to the various purposes for which nature intended it, viz: to form the skeleton of the plant or tree—the glaze on the corn stalk and kernel, the outer covering upon wheat and other straw and grasses, &c. The material of this glaze is derived from that kind of rock called quartz, (sometimes called rock chrystal, or white flint stone;) it is dissolved and rendered soluble by an alkali. Some kinds of trees require a much larger quantity of their structure than others, and produce a much greater amount of ashes upon being burnt. The burning of wood converts it again to silica; the insoluble part of ashes is mostly silex. Oak requires a much larger amount as it is much heavier than pine wood. To prove the solubility of silica by potash, I will state a few plain facts, because we common farmers want facts, and illustrated in a way that we can understand them. From the fact that ley dissolves the silica in wood, tubs for leached ashes are usually made of pine, as they are not so powerfully acted upon by the ley as if they were made of oak. An oak tub, after having been used a few times for a leach tub, would have its silica dissolved, and a stave four inches in width upon being dried, would shrink to two inches, wholly in consequence of the dissolving of the silica (gritty part.) But the ashes do not operate upon the vegetable tissue or fibre of the wood.

When it was the custom of farmers' wives and daughters to spin their thread from flax, the next process was to boil it out in *ley* to soften and remove the harshness of the thread by dissolving the minute particles of silex; but it did not destroy the strength of the vegetable texture. Manufacturers of paper from straw go upon this principle: the straw is boiled in lime water or ley, the glaze upon it is dissolved, and the vegetable fibre is unharmed. From these facts, then, it would seem the alkali acted upon the inorganic rather than upon the organic or vegetable matter.

Dr. Dana's statement of the amount of potash may be correct; but I will try to prove that I am right in my conjecture, as to its being insoluble, and therefore inert. Common granite is the prevailing rock in New England, and is composed of three different minerals—quartz, felspar and mica; quartz is supposed to be of an acid nature; felspar contains 12 to 15 per cent of potash; mica from 5 to 8 per cent of potash. Chemists tell us that the rootlets of living plants and trees have the power of decomposing *granite* rock, to obtain the potash we find in their ashes. 'Tis said, "the living plant is a consummate analist." I will, though with much diffidence, give you my theory of plants decomposing rocks.

The decomposition of vegetable matter always produces an acid—or in other words the decaying or rotting, or more properly the slow combustion of vegetable matter partially converts it into carbon. The oxygen of water combines with the carbon and produces carbonic acid. This acid in its liquid and gaseous form, having an affinity for the alkali in the rock, dissolves it; the alkali dissolves the silica, (quartz) and by the endosmose principle of the living plant, the water holding these in solution is drawn up by the rootlets, and these salts disposed of and assimilated to the purposes designed by the first great cause. In proof of this position, I forward you a piece of rock, not acted upon by the "living plant," but by decomposing vegetable matter, and it will convey to your mind a better idea of my meaning than I can by the pen.

In some situations there is a superabundance of alkali and silica—in others just the quantum needful; and in others a deficiency. These propositions I think I can explain to the satisfaction of you and your readers. Upon the banks of a small river running through this town, there is frequently a strip of land one or two rods in width, and sometimes several rods in length, a few feet above the bed of the river.—Upon every overflow of the banks by a freshet, there is left upon them a deposite of gravel and fine sand; yet every year these strips produce a

tolerably heavy crop of red top grass, generally free from any mixture. When secured in good order for hay, it has every appearance of first rate winter fodder. Yet our cattle will not eat it unless nearly driven to the borders of starvation. Again, there is a similar kind of grass, only more wirey and jointed, growing upon our gneiss and granite ledges, and frequently quite a thick growth of it, where the soil is but two or three inches in depth; it is red top grass, but from its small and narrow leaf and wirey appearance, but few persons would suppose that it was the same kind of grass that was growing within six feet of it, where the soil was deeper. The grass on the river bank, from the comminuted and fine particles of quartz, feldspar and mica, takes on and in such a quantity of silica, that it is hard and difficult to masticate, and probably it is not so nutritious as if grown where there was more vegetable matter in the soil.—That upon the ledges, the roots of the grass rest directly upon the rock and decompose it: this contains more silica, and is harder than that upon the river bank. This establishes my first proposition.

There are other situations where all the necessary constituents for a perfect developement appear to be rightly balanced. With such spots all our farmers are familiar. They are found wherever the wash from rocky or gravelly roads is carried over grass lands, the wheels of carriages and travel on the road are continually grinding to powder the component parts of stones and rocks in the road, which renders their salts soluble. This with the animal and vegetable matters are sprayed over the ground by every heavy shower; the result is a heavy crop of grass. Herdsgrass in such places is frequently found four or five feet in height, standing perfectly erect till mowing time, and affording palatable and nutritious food for cattle.—This I offer to sustain my second proposition.

My third was, that there were others, where there was an absolute deficiency of potash and silica, but an abundance of nutritious matter. Where a piece of land has the wash of a barn, the grass starts early in the spring, and bids fair to yield a great growth of grass; but for want of stamina it frequently falls or lodges before it heads out, and when made into hay it will weigh light according to its bulk: much of this is occasioned by a deficiency of silex. The same results are frequently exhibited on reclaimed meadows, where there is a great amount of decaying vegetable matter. A compost of manure, with a large quantity of ashes and fine sand, is the rich dressing for such spots.

When the primitive growth of wood on our new lands is felled, and burnt upon the ground, and there is sometimes two or three hundred cords per acre, and none of the ashes carried off, we almost invariably obtain a heavy crop of wheat or rye. I have known of more than 50 bushels of wheat or 60 bushels of rye per acre on such lands. The intense heat shivers up the rocks: the great amount of alkali readily dissolve the disintegrated rock, and, in its soluble state, it forms a stiff stalk, with a hard, thick glaze upon the straw, which prevents the rupturing of the sap vessels; the sap, instead of oozing out upon the stalk and rusting, is carried to the head of the grain and fills it with a heavy, plump kernel. The crops of grass that follow for several years correspond with the grain crops, but ultimately the vegetable matter is used up, and nearly all the soluble potash is used up—so that the farmer must resort to the plough, and manure to get a fair crop again.

Every practical farmer who has attempted to raise wheat on highly manured land that has been long cultivated, knows that it is liable to lodge, and very frequently rust or mildew.—These two evils might, I think, be nearly remedied by the application of the right amount of ashes—if that *right* amount could be *ascertained* and *obtained* by the farmer. As to the amount, he need not fear of getting on too much, if he will reflect how much is left upon an acre of burnt land, where two or three hundred cords of hard wood is converted to ashes; but in all probability a *very* much less amount would answer. I conceive there is but little difficulty in any or every farmer's obtaining his supply, by ploughing up a small patch of sandy or gravelly sward land and letting the furrows remain till dry, then commence a fire, with a small quantity of wood, and gradually pile on the sods, and very large heaps may be thus converted to ashes. The vegetable matter would be burnt, the particles of quartz, feldspar and mica would be broken and shivered thereby, rendered soluble, and afford those very salts so essential to a good growth of grain. After the mass had become cool enough to be removed it should be put under cover, to be applied to his wheat ground, after being ploughed in the spring. In all probability fifteen or twenty cartloads would have the desired effect, and the good effects would also be felt for several years by the succeeding crops.

Frequently promising crops of wheat are almost entirely destroyed by rust. On highly manured lands, if there happens to be a day or two of warm, steamy, good corn weather, in July or August, at about the time wheat is in the milk, the rush of sap is so great, that if it do not produce apoplexy, it does that which is nearly as bad—it ruptures the *tender* and *inefficient* coating in the stalk; the sap vessels burst; the sap exudes, and forms a coat of rust, and the crop is nearly ruined. In some of the agricultural papers the last year, I read an account that wheat never rusted where it was sowed upon an old coal heath, and that grass and other crops always succeeded well and were luxuriant. I think this was attributed to the remains of the charcoal; but perhaps a part might be justly attributed to some other cause—to its furnishing a thicker coat of glaze to the grain, and preventing the rupturing of sap vessels.

I might cite a great many more facts in addition, to satisfy any one of the benefit of adding to our cultivated soils, potash in a more soluble state than we find it, as locked up in sand, gravel, stones or rock. You will find some of them in Mr. Colman's 4th Report, viz: Mr. Hagger-ton's compost of peat and barilla; Mr. Jarvis' account of glass factory manure; Mr. Whipple's statements in regard to the value of saltpetre or nitre—that being about one half potash; 102 lbs. of nitre contains as much potash as 79 lbs. of pot or pearlash of commerce. He applies about 105 lbs. to the acre.

But ashes are also useful in agriculture for neutralizing acidity of soils, and for the formation of nitre or saltpetre for agricultural purposes.

In the 6th number, (June, 1842,) of the Farmer's Monthly Visitor, there is taken from the "Albany Cultivator," an article or review of Dr. Dana's Muck Manual. In this article there is a statement made by the Doctor, and another by the reviewer, which I think are calculated to lead to erroneous conclusions. The Doctor says, his first principle in agricultural chemistry is "one rock and consequently one soil:"—from this he lays down his second principle, "that rocks do not affect the vegetation that covers them." The reviewer says, that "rocks certainly exert a powerful influence on the soil that covers them in many cases," but this he says, "is owing to their *physical* condition, and not to their *chemical* constitution." Now, I think, to the mind of every farmer, the plain English of the above would be this: all soils are derived from rocks; all rocks are chemically the *same;* ergo, the chemical constituents of rocks never affect vegetation.

For the sake of many of our farmers, I wish the above was true; but the weak and sickly appearance, and light and short crops of corn, we every year see growing upon soils containing sulphate of iron—iron pyrites, or what farmers more commonly call brimstone rocks, proves the above untrue. There are six thousand of acres of land in this State, that once yielded heavy crops of corn, that now with a dressing of fifteen or twenty loads of manure will not give more than the same number of bushels of corn, and without manure it would not yield five bushels per acre; and this decrease in the amount of crop is almost wholly in consequence of sulphurous or sulphuric acid in the soil, derived from the disintegration of rocks containing sulphur and iron. Hundreds of our farmers have dug solid and heavy rocks from the soil, and laid them into wall, and soon the oxygen of the air and water combines with the iron, and it is decomposed and converted to an oxide or rust; this sets the sulphur free, and that combines with oxygen and forms sulphurous or sulphuric acid, according to the amount of oxygen in combination with the sulphur. This renders the soil acid, and unfortunately the more this land is worked by the plough and harrow, the worse it is, by exposing the stone more and more to the action of the oxygen and eliminating increased quantities of sulphur.

When corn is planted on lands containing this acid, derived from such rocks, it generally looks well and promising for a few weeks, at least as long as the plant draws its nourishment from the decomposing kernel. But after the rootlets on the main roots are formed, and they begin to fulfil their office, by absorbing water from the soil, a re-action takes place and the plant remains stationary for several weeks—the leaves assume a reddish purple color, the main root is corroded or rusted off, to the length of one or two inches, and the farmer generally lays all the blame to worms, while in fact, there may not be a dozen in an acre. After a while a new set of roots start out at the lower joint, but so few and weak, the crop is light, and a large portion of the corn in attempting to cut it, is pulled up at harvesting by the sickle.

I think upon inquiry among farmers having land containing this kind of rock, you will find hundreds that will confirm my statements.—Here the inquiry may arise, is there any remedy? Yes: unleached ashes will neutralize the acidity of such soils, (precisely as salæratus does sour dough,) by combining with the free acid of the soil and forming a neutral sulphate of potash. But I have my doubts about plaster of Paris being useful on such soils, for it is composed of 40 parts sulphuric acid, (oil of vitriol,) and 28 of lime; but the acid is neutralized by the lime, and therefore inert. But reasoning from chemical principles; if we apply to such soils, hydrate or slacked lime, it will combine with the acid of the soil, and the lime will be converted into sulphate of lime—plaster of Paris—and thus remove the free acid from the soil, in the ratio of 40 lbs. of acid to 28 lbs. of lime. It can also be remedied by *very* heavy dressings of manure; but that is not always within the reach of the farmer.

"It is well ascertained that different soils have different properties; prejudicial to the growth of some plants, and favorable to the perfection of others; and it would be a most fortunate circumstance if these differences in the properties of soils were better understood, and more generally acted upon by the great mass of farmers. Notwithstanding the bad character I have given soils containing sulphur in excess, for growing corn, and for many other crops it is equally prejudicial, yet is peculiarly favorable to the perfection of others. In Jones' Conversations on Chemistry," page 136, speaking of sulphur, he says, "it exists in some vegetables, especially those of a *cruciform tribe,*" that is, the tribe of plants consisting of cabbage, turnep, mustard, raddish and cress, of every variety. In some respects this family of plants possesses peculiarities contained in no other tribe.

In the December number of the Genesee Farmer, page 185, there is an extract copied from the Farmers' Journal, England, on soils, by William Chatterly, from which I make the following extract:

"The state of chemical combinations in which the various ingredients of the soil are found, also materially *influences* its fertility, though such combination should differ somewhat for particular crops: for instance, wheat requires that a portion of *silica* should be in un-

ion with *potash:* and for clover, that *sulphur* should exist in the soil in the condition of a soluble sulphate. In confirmation of the above theories, I will relate a few facts that have come under my immediate observation. In 1837, I came into possession of an old farm that had not a furrow plough on it for 20 years. In one of the fields there were 12 or 15 acres that had been yearly mowed all this time, and did not average 5 cwt. of hay to the acre. Many of the rocks and stones in the soil were of the 'brimstone order.' That spring I ploughed about an acre and a half; being, as far as I could judge, the best land of the field, manured with about 20 loads of manure; something over an acre was planted with potatoes, the rest with corn. From the friable appearance of the soil, and the long time it had lain in grass, I expected to have raised a good crop, but in July and August, I observed many of the tops wilted and dead. Upon examination, I found the stalks from the surface of the ground to their roots, entirely corroded or rusted off by some cause to me then inexplicable. I think the crop was less than eighty bushels per acre. The part planted with corn amounted to nothing except for fodder. The next year ('38) all except one-tenth of an acre was manured with about four cart loads of coarse manure, ploughed twice, and sowed with ruta baga about 20th June—harvested 1st November, trimmed close, and accurately measured, and the yield was 100 bushels—or 1000 per acre. In '39, the produce of turneps was very good. The years '40 and '41, in consequence of drought, the turnep seed mostly failed to vegetate, and what few did, the insects destroyed.—The past season, ('42) I planted three small pieces of land with squashes and pumpkins. They were destroyed by the black bug: one of the pieces was set out with ruta baga plants in July; several very warm days succeeded, and the tops were killed to the surface of the ground; and it was many days before they showed any signs of life. When they were harvested in November, many of them were the largest turneps I ever saw. The other pieces were sowed late in July with English turnep seed by merely hoeing them in, and nothing farther was done to them till they were harvested. The product was nearly twenty bushels of as fine turneps as ever I saw. I cannot doubt but the sulphur in the soil exerted a beneficial influence upon the growth of the turneps."

My experience of four years in cultivating clover upon this kind of land, fully confirm Mr. Chatterly's statements; but from the length of this paper I must forbear to go into particulars.

The opinions I have expressed in this communication I trust are correct; what I have stated as facts, I believe are so, but if I am in error, I shall be happy to be set right, as I have no favorite theories that I wish to establish at the expense of truth. LEVI BARTLETT.

Warner, Feb. 1843.

—

Mr. Bartlett's Agricultural Essay, which will be found in this paper, is a masterly production, distinguished alike for sound sense, science simplified, and practical knowledge. It should be *studied* as well as read.—*Amer. Farmer.*

New Reaping Machine.—The editor of the Richmond Compiler was present a few days since at an exhibition of a Reaping Machine, invented by Mr. McCormick, of Rockbridge, Virginia, the operation of which he thus describes in a recent number of his paper:

The machine, placed on small wheels, was moved by two horses around the rye field in which the exhibition took place, at a quick pace, making a clear passage through the grain as it moved, about five feet wide. This it did with a completeness which it is impossible for the cradle to accomplish. This machine would effectually destroy the vocation of the "Gleaner," who has been in times bye-gone, the subject of many a pretty story or pleasant poem. The wheels of the machine keep in constant motion a saw, with edge and teeth not unlike a reap hook, which saws down the grain as it is bent and forced against its edge by a revolving apparatus, resembling a seine reel. The grain falls upon a bed or platform just behind the teeth, whence it is raked by hand. This raking of the grain away is the most laborious part of the process—so rapidly does it accumulate that it is difficult to keep it properly cleared.

AGRICULTURAL SOCIETY.

Mr. Editor—I discover in your paper of the 20th ult., that, after giving some account of the Agricultural Fair of Adams county, Mississippi, you suggest the propriety and importance of organizing an agricultural society for Morgan county. I thank you for the suggestion, and hope that your efforts to promote this most important branch of industry will be *tangibly* appreciated by the public.

I have long wished to see some movement made by which our people might be awakened upon this subject. I have, therefore, concluded to submit a few reasons in support of the suggestion you make. Morgan county once sustained double her present population, and supported it profitably to the occupants of her soil. Why is this? Her territorial limits have not been contracted. The answer is an easy, though a very melancholy one: one acre of her soil would then produce what three will hardly do now. The consequence is, that our population is yearly decreasing—many of our most valuable citizens are leaving us, and are going in search of more productive land.

Can these things be remedied? I answer, that what has been done in other places is, at least, worth the effort with us. We know that in many portions of the world, so far from exhausting lands by cultivation, they actually enrich them yearly. The truth is, we have been spoiled by having had allotted to us by the Almighty a rich freehold—well adapted to the culture of the great staple of this country. Like a profligate heir, we have been reckless of our inheritance, till we begin to find, like him, that the best estate may be ruined by perpetual drafts on and none in favor of it. Let us then profit by experience, and begin to husband our remaining resources, and try to regain by a well organized system, what we have lost by the reckless prodigality of our soil. We have every inducement to improve our lands; in the first place we have a soil highly susceptible of improvement—our lands being mostly based upon good clay foundations; and again, our county occupies a position in the State in point of locality, which, with its health, temperature and good pure water, will make it at all times a desirable place of residence, and will not only induce our population to remain, if properly cultivated and improved, but will induce others to come amongst us. These are reasons of a local character. I might, if I did not fear of trespassing too far upon your limits, give many more of a general character. I will, however, submit but one or two: I think it could be demonstrated that, by adopting a system of cultivation, by which we retain what soil we have, and augment and improve the same by the proper collection and application of manure, we shall not only add yearly to the value of our lands, but produce more profitable crops.

Again, it is melancholy to look upon any thing, animate or inanimate, in a state of decline—hence, you will always find more of energy and vigor in a newly settled community. Every thing there has a tendency to buoy up and give elasticity to the spirits. Well, if this be true, what must be the effect produced upon the mind of the way-farer, who jogs up and down our high way (and especially if he had traversed the same path some twenty four years ago,) where once stood the poplar, the walnut and the red bud, he beholds now the deep-washed gully, with here and there a patch of broom-sedge, and, per chance, a bunch of the blackberry-bush, that has taken sustenance from the decaying roots of some friendly stump, or that of some vagrant log. No wonder you hear so much complaint of "blue devils." But lastly, the system of cultivation (or of land butchery) hitherto pursued in the country, has been such as to hold out but one solitary inducement to embark in it, to wit: the profits in dollars and cents, and that is now pretty well over. How often have you heard the young man say, "I can't think of planting—I've taken too much pains with my education to busy myself in that way." Hence the learned professions are all overstocked, and loafers "abound in the land." The truth is, that a young man of cultivated mind can find nothing to facinate in our farming, because we have neither science nor system in it. The most ignorant African could have the advantage of him, for he *would* have some experience. How desirable, then, so to improve this, the support of all other professions, as to allure the talented and enterprising to its embrace; to sweeten labor by converting drudgery into scientific experiment, and so stamping mind upon the laws of nature, as to bring up, out of our present confusion, the most beautiful system. I will not extend this article by way of giving reasons why an organized society will be necessary to the promotion of the objects here spoken of—they must be obvious to every one. I will suggest a meeting of the planters of the county at some early day to take the same into consideration, that a society may be organized; and I think of no time more appropriate than the Anniversary of our National Independence.

PLANTER.

—

Mr. Editor—Your correspondent "Planter" suggests the importance of an Agricultural Society for Morgan county, and gives us some of the reasons that should influence our people on this subject. I most cordially agree with him in the views which he has taken, and would now add a few additional remarks. That the *subject* of agriculture is one of importance, demanding our first attention, and our best efforts, is a truth as palpable as it is of profound interest to our well being in society. The *first* employment of the *first* man was the cultivation of the earth, and his first descendants were not too *proud* or too *lazy* to imitate the example of their great progenitor; nor have some of the *first men* of our day deemed the *subject of agricultural science* too little and grovelling to engage brains that teem with scientific lore.

If the importance and utility of the subject would then command our first attention, why not secure every and all the means that shall lead to the most triumphant results? If agriculture be purely practical, then let us lend our physical energies to its attainment; but if it be both theoretical and practical, why then let us collect the various theories and practices of men of diversified acquirements and varied locations of country, as well as a difference of soil and climate. I ask, now, how can all this be effected better than by the formation of an Agricultural Society? Here we occasionally meet and tell over our enterprizes with our dear old mother earth—we recount to one another our fraternal kindness, and tell of the food with which this mother was fed—how artfully we succeeded in the preparation of her nutriment—how we regaled and electrified the old matron when we dosed her with our gaseous compounds, and made her joy so extatic that even heaven poured smiling tears upon her, and she, in the exuberency of her joy, bestowed upon her sons the golden treasures of corn, and cotton, and wheat, and all that could fatten and make alive the animate creation.

It is, thus, by mutual interchange of opinions, that we form conclusions and arrive at truths that are of practical importance to mankind. It is in this way that the agriculture of England and Scotland, Germany and France, have attained its present elevated and enviable state. It is by knowledge diffused through Societies, in this way, that processes once considered difficult and mysterious are now made familiar to all. We hold converse in an Agricultural So-

ciety with Sir Humphrey Davy, Chaptal and Liebig, and are made to know how chemistry and her kindred sciences subserve the purposes of man, and how the various manures are prepared and assimulated to the wants and perfections of the vegetable kingdom. We thus, in a word, learn by associations of this kind, to combine and concentrate scientific agricultural knowledge to all the practical purposes of life.

But, again: an Agricultural Society would stimulate us to action—first, by reading works connected with the subject; secondly, by the carrying out of any theory that we might regard as useful; thirdly, by an actual exhibit, before the Society, of what had been the result of our labors, and lastly, by the pleasure that we would derive from having premiums awarded to those most skilful and successful in their operations.

But again, sir, I have long looked upon our community as destitute of that source of rational enjoyment in which all might be participants without a sacrifice of moral feeling or moral principle; now, here, at a well regulated Agricultural Fair, held annually or semi-annually, it seems to me all might participate in the joys and festivities which could be thrown around an occasion like this. The sage farmer of sixty years, and his son of twenty, with the dignified old matron, and her daughter of blooming sixteen, with all the other avocations of life, might assemble here, and whilst this sage farmer would tell you in strains the simplest of the simple, how it was, under the blessing of God, that he ploughed up his soil, and applied his compost manure, and reaped his harvest of gold; the aged matron, with her fair daughter, would tell how it was that she succeeded so well in the brilliancy and permanence of those colors that made her domestics the gaze and universal admiration of all around. These recitals would tell upon the youth of the country, and catch their admiring gaze, and thus they would discover something in agricultural pursuits that would be *attractive.*

If we look around us we must come to this conclusion, that if any country upon earth deserves to be improved, we have that country.—We are indebted to improvement upon two counts; first, by butchery and then murder, we have ruined one of the best portions of the habitable globe, either directly or as accessories after the fact, and are, therefore, bound for its restoration; and secondly, as good stewards, we are bound for the improvement of the talents committed to our charge. We could not, therefore, occupy our county, as it was *originally*, without being under obligation to its improvement; and just here I know we do not feel this moral obligation, or else we would be doing more than has heretofore been done in this important matter. The question now arises, how can this improvement be effected? I answer, by Agricultural Societies, as furnishing information and offering stimulants to the community in this great and laudable enterprise. But, says one, all these Societies are alike—a mere *bragological humbug*—a safety valve through which a few loquacious, babling, senseless dolts may pass off their steam, and there the whole machinery stops. Well, I admit the force of the objection, (for it has force,) but if in letting off the steam it should drive a few men to action, through whose instrumentality our national wealth shall be increased a few hundred bushels of wheat or corn, then the Society will, at least, have done no harm; and if in this day of "humbug" no *harm* is done, we shall deserve commendation at the hands of our countrymen.

But, sir, I am almost deterred from sending you this communication, and why? Because it is too true that those who talk the most usually perform the least, and that we scarcely see blended in the same man many words and many actions; hence, sir, I may anticipate the charge of being an agricultural writer, without being an agricultural worker or producer. But to be more serious on this subject, I ask what are we doing, or do we believe that any thing can be done, to improve our lands? Have we determined upon any system of farming, and have we begun even with our acre of land to carry out this system? Have we made any preparations about our barn yards for manuring? or have we determined that it is *easier* to call in the neighbors and move the barn to a new place, than to go to the trouble of moving the manure from around the barn? Is there any thing to be learned from the age in which we live? If so, where shall we go, and how shall we learn it? Must we rely upon no other sources than our observation and experience for all the information we desire? You perceive these are questions of importance, and mainly connected with our interest and future prosperity.

I would suggest, sir, that a meeting take place preliminary to a meeting on the 4th of July, at which meeting a constitution and bye-laws could be prepared and then submitted to the subsequent meeting in July. The time has arrived when, I think, our farmers are ready for a Society, and will respond to a call made on them at any time and place. PLANTER No. 2.

Southern Miscellany.

AMMONIA.

Since the publication of Liebig's work on vegetable chemistry, it has been assumed that the ammonia constituted the most valuable part of stable manure. To arrest and retain this volatile gas, then, has been the great desideratum. The use of plaster, the sulphate of lime, has been recommended for this purpose. It is advised to be strewn over the stable litter before it is removed from the stall. In this case, Liebig says, a double decomposition will take place, from which will result sulphate of ammonia and carbonate of lime; by this means the ammonia will be retained in a soluble shape for the use of plants. Mr. Patridge, of New York, who proclaims himself a practised and experienced chemist, denies that any such action will result from the combination, at atmospheric temperature. Now, *non componere lites*, that is not for us to decide when doctors disagree.—But we see it recommended, possibly by way of settling this vexed question, to scatter common salt on the dung heap, or to water the litter of the stalls well with strong brine, an hour or two before removal. From this mixture result, it is said, muriate of ammonia and carbonate of soda. In noticing this suggestion touching the salt, the editor of the American Farmer, whose practical experience is worth a hundred theories of the most learned chemists, says,

"We are not chemist enough to avouch for the action of salt in the manure heap as above described; but this we can state, that some years back, we bought twenty barrels of rotten fish to use as a manure for corn. In each of these barrels there were about half a bushel of fish salt, of course highly charged with the oil of the fish. After using the fish in the hills of corn, one to each, we mixed the salt with ten loads of barn yard and stable manure, suffering it to remain a few days, when we turned it over with the shovel and gave it a more thorough mixing. We then hauled it out to the field, and spread it on one half an acre; on an adjoining half acre, we spread ten other loads of the same manure, but unmixed with salt. We ploughed up the piece of ground and planted the whole in corn. The half acre of corn planted on the ground fertilized with the salted manure, grew from the start more luxuriantly, looked of a darker green throughout the season, and yielded more grain than that on the adjoining half, though the soils were precisely alike, and each had received the same quantity of barn-yard and stable manure, and the same culture. The blades on the salted part maintained their greenness until pulled, although those on the other part, when pulled, were considerably *fired.* It is here worthy of remark that the ears on the former were some days later in hardening.

"We have stated the above fact, and without refering the result of our experiment, at the time, to any chemical combination between the salt and the ammonia of the manure, we were induced by our observation of the effect produced, to conclude that the *salt* used, had imparted to the earth the *capacity of attracting* from the atmosphere more moisture, as well as that of preserving it longer from the evaporating influence of the sun's rays; for the surface of the earth always looked, and was, in fact, much more moist than that of the contiguous piece of ground. What we looked upon at the time as unevaporated *dew*, may have been the *ammonia* abstracted from the atmosphere, and fixed thro' the chemical agency of the salt upon the surface, and there made to await absorption by the earth, thence to be taken up by the roots of the plants as nutriment. If this union takes place, and we have no right to question it, for the result of our experiment would seem to corroborate the assumption, SALT must form a most valuable acquisition to the dung heap, as any substance not too costly, which can give fixedness to the eliminating properties of manure—which can prevent the escape of the rich gases—must operate greatly to the advantage of the husbandman, because it would impart to his fertilizing materials, a degree of durability which alone they do not possess—and this property of salt, we should think, would be greatly increased in value, in sandy and other porous soils, where, as it is known, the effects of manure are much less lasting, owing to the escape of its volatile parts.

"But whether the chemical action imputed to the salt be as stated or not, we have no hesitation in affirming, that every farmer who can afford to incur the cost, should procure a few bushels per acre, to mix with his manure intended for his corn ground, as it would prevent injury from the cut and grub worm, as was proved by our experiment; for although the corn on that portion of the ground where the unsalted manure was used, suffered greatly from the ravages of these enemies, that on the part where the salted manure was used, escaped without any injury from them.

"The quantity of salt used by us was greater than we recommend. It was at the rate of 20 bushely per acre; having it, we used the whole as stated; but we think that five bushels per acre would have answered equally well for the time being. In other experiments which we have made with salt, in sowing it broadcast over turnep ground, after it was manured, plowed and harrowed, we only used six bushels per acre, and witnessed the finest effects from it on a corn crop grown on the ground the succeeding year."—*Southern Planter.*

REARING CALVES.

Messrs. GAYLORD & TUCKER.—I maintain that the way nature points out for animals, is the most proper for them. At any rate, if a calf sucks from a cow half that she gives, it benefits him more than though the same be fed to him. Of this I am positive. We generally take a cow that gives a good mess, and let two calves suck her, and they frequently get quite fat with this chance, seem to wean better, winter better, and make thriftier cattle than those we never let suck. Around the bars of the calf pasture, you can easily make a pen with four or five boards and a few stakes; stick the stakes one or two inches apart; put a pin through them for the board to rest on, so high that the calves can run under them. Let me use this pen, and you may use your stool, and I will feed ten calves my way, quicker and better than you would two the old way, by milking and feeding in a pail; and I think my cows would give the most milk too. A couple of calves striving to get more milk every time, I think would have a tendency to increase the quantity, or else nature has not provided for this emergency as she has for other ones.—*Albany Cultivator.*

TO PREVENT THE FLAVOR OF TURNEPS ON BUTTER.—A little saltpetre added to the cream just before churning, will prevent the disagreeable flavor arising from the feeding of ruta bagas.

REPORT

Of M. Dumas to the French Academy on M. Boncherie's process of preserving Wood.

TRANSLATED BY EDWARD TILGHMAN, C. E.

The Academy having charged M. M. Arago, de Mirable, Poncelet, Gambey, Audom, Boussengault and myself, with the examination of the memoir of Dr. Boncherie on the preservation of wood from decay, we proceed to the accomplishment of this duty.

The Academy has already beheld the preparations of the author with so great an interest—it has, at this moment, such remarkable specimens of the process before its eyes—that the labor of its Committee, in some respects at least, is greatly abridged.

Dr. Boncherie proposes te render wood much more durable, to preserve its elasticity, to prevent its warping from alternate exposure to dryness and moisture, to diminish its combustibility, to increase its tenacity and hardness, and, lastly, to give it colors and even odor the most various and durable. All these requirements are obtained by novel, simple and economical means, and by the aid of common and low-priced materials. To impregnate an entire tree with the proper coloring, or preservative material, our author has recourse to no complicate mechanical means; he avails himself of the natural suction of the tree itself, which is sufficient to raise from the base to the highest branches, the liquids he wishes to introduce, provided that they are maintained at a certain degree of concentration; thus, when a tree is severed from its roots the end is plunged in the liquid you wish it to imbibe, which, in a few days, ascends to its topmost leaves and pervades the whole vegetable tissue. It is not essential that the tree should retain all its branches or leaves—a few branches at the top is sufficient to induce the necessary suction; neither is it requisite that it should always be preserved upright, which would often render the operation impossible.—Having cut it down and deprived it of its useless branches, the butt is then placed in contact with the liquid to be absorbed, which penetrates the wood in every part. Finally, it is not even necessary to fell the tree, for if a cavity be excavated at its base, or a transverse saw cut be made through a portion of the base, it will afford sufficient contact with the preservative liquid, and the absorption will be as rapid and complete as before.

The impregnation which is thus affected in a short time, without trouble or expense, will be found to be a different process from those hitherto made to impregnate wood already cut, have been effected by the action of the most powerful machines, or by the prolonged effect of the liquid in which it was submerged. The novel and ingenious process recommended by Dr. Boncherie subjects to human industry an immense natural force, and permits it to introduce without labor, into the most delicate vegetable tissues, any soluble substance it may be thought useful to place there. If our author has solved the grand problem he proposed to himself in the most simple and practical manner, he has not evinced less sagacity in the choice of materials necessary to produce the desired effects as to preservation, &c. To increase the durability and hardness of wood, and to prevent the wet and dry rot, he introduces into its pores the pyrolignite of iron: this substance is chosen because it is produced by pyrolignious acid, which is to be obtained in any forest where charcoal is made; this acid is easily transformed into pyrolignite of iron by putting it in contact, even when cold, with old scrap iron. The liquid thus prepared is replete with creosote, which, of itself, without the salt of iron, hardens and preserves wood as well as defends it from the attacks of insects.

Official experiments have been made at the fungus pits at Bordeaux upon hoops (circles) prepared by the author, which have resulted in establishing, in the most triumphant manner, the great durability of wood thus embalmed.—The unprepared hoops crumbled to pieces at the least touch, whilst the others were as sound as when first placed there. To prevent the warping of wood, to preserve its elasticity and diminish its combustibility, our author has recourse to the use of the chlorides which have nearly the desired effect. Fully impressed with the conviction that his process must shortly come into universal use, he is not content with the chloride of lime, already so cheap, he has experimented upon the sea water of the salt marshes, a costless material, in which he has found all the desirable qualities. Wood prepared with these saline solutions, preserves its flexibility when exposed to the air many years; in their strips it may be bent and rebent the contrary way in a spiral without breaking; neither will it crack or warp from the greatest extreme of dryness. Lastly, it will not burn, or, at least, with such difficulty as to be easily extinguished.

To these great and useful properties, which the naval constructior and civil engineer will appreciate and profit by, our author has added others, which, without being so importantly useful, promises to afford new methods and materials to the arts. He colors wood in clouds so various and so beautifully curious, that the cabinet maker will find it to his advantage to use the more common woods in lieu of the more costly. The specimens of these preparations now before the Academy relieves us from all detail; it will be sufficient to observe,

That the pyrolignite of iron, when used by itself, produces a brown tint of the same color with those knotty parts of the wood where the liquid cannot penetrate.

When the pyrolignite is succeeded by any tanning liquid it produces ink in the body of the wood, and we obtain, by these means, a blue-black or grey. A Prussian blue is caused by the absorption of the pyrolignite immediately by the prussiate of potash.

By introducing successively acetate of lead and chromate of potash, the yellow chromate of lead is produced.

We may produce the most various and beautiful effects by introducing simultaneously the pyrolignite of iron, the prussiate, the acetate of lead and the chromate of potash, which cause blended clouds of blue, green, yellow and brown.

Thus we find our author does not confine himself to the introduction of one liquid only, but causes many to enter the same vegetable, and thus produces any modification of color he may wish; these solutions, causing such diversity of color, may be varied almost to infinity. Chemistry is rich enough in reactions of this kind to satisfy the most fastidious caprice. We will not here speak of rendering wood odoriferous by impregnations of this nature; it is an application too easily understood and too much confined, to mere luxury to compare in importance with the more useful details already given.

* * * * *

The remainder of the report is omitted as containing nothing of interest to the general reader; the rival claims M. Millet D'Aubenton to the honor of the discovery are mentioned, and very shortly exploded, and the report concludes by recommending that the Doctor's memoire be published in the Recueil des Savans etrangers. —*Southern Miscellany.*

CURE FOR MANGE IN SWINE.—A correspondent of the Maine Farmer says:—Take raw tobacco, steeped in cold and strong chamber ley, pour off the clear liquor, then mix it, equal parts, with lamp oil, and then rub on the composition. It is a safe and sovereign remedy for mange, in all stages and all animals, brute or human.—This ointment, if kept in a tight bottle, will keep good any length of time. It should be well shaken together when used, for the parts soon separate when standing.

TO CURE SCRATCHES IN A HORSE.—Wash the legs with strong soap suds, and then with beef brine. Two applications will cure the worst case.—*Cent. N. Y. Farmer.*

RYE TURNING TO CHEAT.

LA GRANGE, N. C., May 25, 1842.

Messrs. EDITORS—I have taken a seat at my writing table to assert a fact or principle in nature, which I have heard disputed time and again; but I think I shall be able to corroborate my assertion with such evidence as to convince the most sceptical—but to the subject. During last summer I fallowed two acres of land adjoining my meadow, for the purpose of sowing rye. About the last of August I sowed the rye, and ploughed it in with gophers, and then harrowed it over, and it soon came up very thick. However, it grew off well and covered over the ground nearly before cold weather.—Thus it remained until in January, when the weather was so warm that the rye started out and seemed to be on the eve of jointing, but the cold weather that came on in February checked it and killed some of the under blades, but it did not appear to be seriously injured until our *March winter*, after which I noticed that nine-tenths of the bunches were without the least appearance of life, and remained so about a fortnight, when out of these *death-like* bunches there came very luxuriant young rye, (as I thought,) and continued to grow finely, but it did not seem to keep pace with the scattering rye that was not killed out by the freezes; I therefore turned my horses on it for the purpose of eating off the forward bunches, so as to make it more evenly; this being effected, there was no more grazing done on it for some weeks, when to my utter astonishment I discovered that all the bunches that had been seemingly killed was producing CHEAT instead of rye. Now, here is the case,—the rye being sowed very early, was rapidly advancing towards maturity before it was overtaken by the cold weather, which held it in check until that very remarkable warm weather in January, when it put forth as if winter had been over; then the cold of February and March completely destroyed the germs of all those bunches whose roots were still alive, and afterwards put forth suckers, which is the cheat, for I, in examining, found a bunch, (which was from one grain of rye,) with rye and cheat both proceeding from the same root, and the blades of the cheat are broader than I ever saw before, and have somewhat the resemblance of rye, some of which are ⅝ of an inch in width, &c.

I noticed an editorial article in the last number of the Advocate, relative to the blast in oats, which embodies good sound ideas, no doubt.—But my experience on that subject has confirmed me in the following notions, as relates to the cause of smut or black heads in oats, as well as the remedy to arrest or dissipate that disease.—1st, sow ripe seed in due time, which is soon as the ground can be caught in order after the 20th of February; (for here I will take the liberty of saying that my oats were all sown and were exposed to the snow and freezings of last March, and I never had finer looking oats at this season;) those intended for seed should be allowed to stand until fully ripe, some three or four days longer than those intended for food. The seed oats should by no means be wet, or even damp, by dew or rain, when bound, but dry and bound in small bundles, and then housed or stacked before getting wet, if possible. The above is our course, and we seldom suffer any loss by the above mentioned disease in oats.

Yours, respectfully,

D. W. C. JOHNSON.

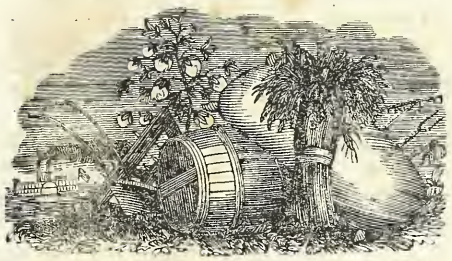
P. S. I believe the cause, or at least the prime cause of smut in oats, is cutting the seed oats too green; and also damages received by being over-heated in bundles or stacks. It is therefore of great importance to be very careful of the oats intended for seed. D. W. C. J.

REMARKS.—We know that the views of our correspondent, Mr. J., in regard to other grain turning to cheat, has in years past, been very generally entertained—but had come to the conclusion, that in this enlightened day the opinion was nearly exploded. We have no wish to be drawn into a controversy on the subject; but we would just as much expect to see peaches grow-

ing on coins produced from the stumps of an apple tree, as cheat produced by a grain of rye or wheat. And moreover, a premium of $100 was offered by J. J. Thomas, one of the editors of the New Genesee Farmer, about two years ago, for a specimen that would satisfactorily substantiate the fact of such change. We have not yet learned that the premium has ever been claimed, and we are not apprehensive that such a specimen will ever be produced.

We have no kind of doubt that Mr. J. is fully convinced that his rye was changed into cheat. But had he been as unbelieving as we are on that subject, he would, no doubt, have made discoveries that escaped his observation.

N. C. Farmers' Advocate.



WEDNESDAY, JUNE 21, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

OUR VOLUME.

As the present number concludes the first half of the first volume, it may not be improper for us to say a few words to the friends of the enterprise. In entering upon the duties of publishing an agricultural work at the South, we were not unadvised of the difficulties we should encounter in prosecuting the labor. We are the pioneers in Georgia—the planters generally had not accustomed themselves to consult theories and to investigate the experiments of others in the pursuit of their labors—indeed, they had followed so long in the beaten track of their fathers, that we anticipated no little opposition, and not a few sneers at the introduction of what is usually denominated *"book farming."* We are happy to perceive, however, that the prejudices of a large portion of the people on the subject are rapidly dissipating, and we confidently believe that the day is not far distant when the great mass of our planters will be constant patrons of an agricultural paper. This feeling is daily manifesting itself by the continued and rapidly increasing circulation of the "SOUTHERN CULTIVATOR," and the interest which seems generally to be excited in its behalf. Indeed, we may almost assert that it is already placed on a firm foundation, and will certainly become one of the permanent agricultural periodicals of the country, such is its present prospects, which we confidently believe will be fully realised.—For its success we have to thank numerous friends in various sections of the country, who have interested themselves in its behalf; and particularly are we under obligations to the press, for the very flattering notices we have received from our brethren of the corps editorial, to all of whom we return our most sincere thanks. Although we are well aware that our little sheet is far surpassed by some of the Northern periodicals, whose facilities for publishing an interesting and valuable paper are much greater than ours, nevertheless the very flattering reception which the "Southern Cultivator" has met at the hands of Southern planters, while it gives earnest of the future, testifies, in the most grateful terms, the estimation in which it is held by them. And we sincerely trust we shall go on and continue to ingratiate ourself more and more into their favor, till we have attained the highest point of our ambition, the rendering the work among the most interesting periodicals in the country. This we will do if the planters will give us their countenance and support, for which we feel confident we shall not plead in vain.

TO CORRESPONDENTS.

In returning our thanks to our friend FARRAR for his communication in this number, containing as it does so many valuable practical hints, we avail ourself of the occasion to repeat what we have before said to our planters on the subject of writing communications for the press.—We know that very few of you are accustomed to write for the press, and you therefore feel some delicacy in doing so. This should not be—you do not hesitate to tell your neighbor, or even a stranger when you meet one, what you have accomplished by this or that experiment, or what improvement you have made by this or that system of culture. Then why feel any delicacy in telling it to every reader of the "Southern Cultivator," in the shape of a communication? We have before said to you, give us your facts and experiments, and tell them in the same easy, familiar style that you talk to your neighbors, and if you should happen to spell a word wrong, or write an ungrammatical sentence, we will make all these corrections for you and put it in ship shape. You need not, therefore, feel the slightest fears about your spelling or diction.

DOMESTIC SILK.

Accompanying the communication of Mr. CASSEDY, which will be found in this number, we received seven skeins of very beautiful sewing-silk, equal, if not superior in strength, to the Italian, and only inferior to the imported article in the lustre imparted in the dying and finish. Indeed, with such specimens of native silk as that now before us, we think it not at all extravagant to anticipate that the day is not far distant when the culture of silk will become an important branch of Southern production. It is yet in its infancy, 'tis true, and much has yet to be learned, but we doubt not that the enterprise and industry of our citizens will accomplish all that may be attained, particularly when we reflect that the low price of their great staple necessarily will drive many to seek some new enterprise for the distribution of their labor.—We therefore hope that those of our citizens, who have an opportunity, will continue to make experiments by way of testing its utility,—and we suggest to all who feel a disposition to make such experiments, to pursue the Italian system of culture rather than the French. The reason for this is very obvious—the climate of Italy is quite the same as our own, while that of France is much colder.—It is, therefore, important that we should adopt that system of culture which long experience has established in those climates approximating nearest our own.

CULTURE OF GAMA GRASS.

I feel much gratified by your excellent remarks on the subject of the Gama Grass, in your valuable periodical of the 19th April last. A practical knowledge of this plant for the last twenty years, and having given the first impulse to public attention towards it in the South and East, I feel some more than usual interest in it, especially as this acquaintance and experience compels a belief *that it is yet the most valuable grass for animals*, and for the interests of the cultivator of the soil, *considered in every point of view*, wherever the locality is found favorable, that is yet known. From the nature of the remarks that I have read regarding it, it is evidently ranked by some gentlemen amongst the coarse grasses. On this part of the subject, I must remark, that the degree of coarseness depends on the mode of cultivation, and the *stage* at which it is cut and used. At fifteen days' growth, I must contend that it is among the most delicate known, more nearly resembling the blue grass than any other.

Taking your judicious replies to the queries proposed as they stand, to the first I beg leave respectfully to add, that my first and so highly successful essay to cultivate this grass, was on a *fine* sandy land, with a red clay foundation, dark grey surface about six inches; although some of the finest specimens that I have ever seen are found on the low grounds of the Tombigbe, and the black rich limestone prairie lands of the Choctaw nation, in about 32½°.—Another splendid growth, say many acres in a body, is found in a state of nature, twelve or fifteen miles east of the Tombigbe, on the rotten limestone land, bordering a small creek.

2d query.—For a perfect cultivation of this grass, *trench* plough as deep as possible, previous to setting a piece of ground with this grass; let the largest bar-shear be followed by a proportionably large scooter, or bull-tongue plough; and, if possible, cross the land in the same way, recollecting this extra work is only once during a life time. Pay no attention to the foundation of your soil, but loosen deep. To prepare other land in the way to produce the most lasting and successful growth, I spread, previous to the first ploughing, a heavy coat of manure. I admit the cultivation will cause the manure to *sink*, but not half as *deep* as the *roots* will penetrate. At the second preparatory ploughing, I lime, if the soil is any other than rotten limestone land or prairie; I prefer entirely raising the plants on a bed and setting the land, as in the case of the tobacco plants, and set them fifteen inches apart every way. Here, it must be recollected, that the disposition of this plant to spread its roots, as well as to go down perpendicular, is such that at even two feet from plant to plant the cultivator cannot calculate on giving this field of it more than one ploughing, or two at most, the first and second year after setting out the plants, and indeed, during his life. This can be done safely the first and second year by running a bull tongue with a small mule, guided by a careful ploughman, between the rows, each way twice in the same tract. All after cultivation must be with the *pronged hoe*. With this tool, well made, a skilful hand will clean and loosen the ground at every hoeing nine to twelve inches.

Query 3d—Fully answered. 4th—Cut it with a sickle or scythe; what you cut, scatter as fast as cut, before *twelve* o'clock; if the weather is *clear*, turn over next morning after the dew is off the grass, and stack after 12 o'clock, sprinkling salt liberally while stacking, for hay cut every thirty days; not a grain of the salt used will be lost. 5th—After gathering the seed, throw them into a vessel, mixing with them any moderately moist sandy soil, keeping the vessel in a cool and rather damp place, until planting time. 6th—If perfectly cultivated for hay, this

grass must be cut every thirty days; or if for soiling horses, cattle or mules, the same age is proper, from the 1st May to the 1st November, in lat. 31 to 33. For a milch cow, to produce the finest of milk and butter, cut every *fifteen* days; it will then be found 24 to 30 inches in height; if cut monthly, from 36 to 42 inches high. After the first cutting, leave a few rows for seeding. 7th—Of *green* grass, the product, cultivated as heretofore stated, will be found from 150 to 250,000 pounds per acre per annum. At each cutting, loosen the ground between the rows with the hoes before mentioned; and to procure the greatest possible product, scatter manure after the *second* cutting. The relative value of this grass I was *compelled* to test. I cut it with a sickle, bound into small sheaves on the fore part of the day, after the dew was off, at thirty days' growth. With one of Mr. Eastman's cutting boxes I cut it up, say an inch in length; this was done for feeding in the after part of the day, and cut at dinner time, while the animals were eating, for night feeding. I gave each mule as much of the cut grass as he could eat, together with a tin cup full of Indian, rye and pea meal, strewn over it, with salt proportioned.

My oxen, engaged in hauling, I fed in the same way. I never had more or better work done, or healthier animals. The cutting of the grass in a lot adjacent to the stable was done during the time the animals were allowed for eating, nooning, &c.—no time lost.

In feeding with this or any other green grass, I add a small quantity of rye, oats, barley or rice, cut on the sheaf, and mixed with the grass.

Some farther remarks hereafter.

AGRICOLA.

South Alabama, 1843.

American Farmer.

HEAD AND HAND LABOR.—The Bangor Whig has the following excellent remarks on the subject of labor:

What honest vocation can be named that does not contribute, in a greater or less degree, to the enjoyment of men? It may be humble, indeed, but it goes to swell the mighty aggregate; it may be the rill that trickles from the mountain side, but it diffuses fertility through the valley, and mingles its drops at last with the ocean. The true American motto is and must be—marked upon our foreheads, written upon our door post—channeled in the earth, and wafted upon the waves—*Industry—Labor is Honorable*, and idleness is dishonorable, and I care not if it be labor, whether it be the head or the hands. Away with the miserable jargon of the political economists, who write so complacently about the producing and non-producing classes. It has no foundation in nature or in experience. Whitney, whose cotton gin doubled the value of every acre of land in the South, raised more cotton with his head than any twenty men ever raised with their hands. Let me exhort those of you who are devoted to intellectual pursuits, to cherish, on your part, an exalted and a just idea of the dignity and value of manual labor, and to make that opinion known in our works and seen in the earnest of our action. The laboring men in this country are vast in number and respectable in character. We owe to them, under Providence, the most gladsome spectacle the sun beholds in its course—a land of cultivated and fertile fields, an ocean white with canvass. We owe to them the annual spectacle of golden harvests, which carry plenty and happiness alike to the palaces and the cottage. We owe to them the fortresses that guard our coasts—the ships that have borne our flag to every clime and carried the thunder of our cannon triumphant over the waters of the deep.

FOR MAKING CLOTH WATER PROOF.—Immerse the cloth in a solution of Alum for 10 minutes, air it for 20 minutes, then immerse it in pulverised chalk.—*Cent. N. Y. Farm.*

DOMESTIC SILK.—This new branch of industry is fast becoming a profitable enterprise thro'-out the country. The Southern States are particularly favorable for the growth of silk—there being not only the climate in its favor, but an immense amount of unproductive labor on our plantations, which could be employed in the culture of silk, without distracting from the usual and legitimate business of the planter.—The children and aged persons, who now sit about "the quarters," and bake in the sun, might find it a pleasant enjoyment to rear the silk worm; and the planter would find it very beneficial to his purse. The silk business, however, recommends itself particularly to small capitalists. They would find it well worthy of their notice, as it presents the most profitable investment of mere labor, and may be successfully pursued with the smallest amount of capital. The process of silk raising is very simple; there are many farmers' wives who, with no machinery or chemical wares whatever, except what is found upon every farm, that manufacture sewing silk of a quality superior to any brought from foreign parts; and we would say that stockings knit from the silk are not only the most beautiful exhibition of domestic skill that can be seen, but the most durable and pleasant article of dress that can be imagined. A few ladies in the South have set the example of silk raising, and manufacturing it into articles of use. No one who visited the State fair at Baton Rouge last year, will forget some beautiful specimens of shawls exhibited by a lady of West Feliciana.—*N. O. Sportsman.*

THINGS TO BE REMEMBERED.

Horses should never be put to severe work on a full stomach. More horses are hurt by hard driving after a full feed, than by a full feed after hard driving.

If the farmer wishes to have his pork barrel and meal chest hold out, let him look well to his kitchen garden. Plenty of vegetables conduce not more to health than to profit

In laying in a stock of winter fodder for animals, let it not be forgotten that a little too much is just enough. Starving animals at any time is miserable policy.

As you treat your land so it will treat you. Feed it with manures liberally, and it will yield you bread bountifully.

Avoid debts as you would the leprosy. If you are ever tempted to purchase on credit, put it off for three days. You need time for reflection.

Never beg fruit, or anything else you can produce by the expenditure of a little time or labor. It is as reasonable to expect a man to give away the products of his wheat field, as of his orchard or fruit garden.

If you keep your sheep and cattle in your meadows until June, don't complain next winter because you are compelled to purchase hay for your stock.

The man who uses good seed, has a good soil, and works it in good season, rarely fails of having a good crop to reward his toil.

Never forfeit your word. The saying in truth, of any farmer, "his word is as good as his bond," is worth more to him than the interest of $10,000 annually.—*Albany Cultivator.*

SCAB IN SHEEP.—This, says the Genesee Farmer, is one of the most troublesome diseases to which sheep are subject. Its prevalence at times, is the cause of severe losses, particularly to those who keep large numbers of these animals, and to whom an efficient and speedy remedy is unknown. The following article on the preventive of this pest, contains sound advice, and as it is published over the gentleman's own signature, is probably entitled to regard:

"This being the proper time to give the information, I send you an account of the manner in which I treat sheep affected with the scab.—I recommend that sheep be put in a newly burned fallow as soon as possible after shearing.—People are careful to avoid the blacking of sheep, but I think it a sure remedy for the scab, and also for the foot rot. Let them have access to a piece of burnt ground as fresh as possible. Leave down the fence from the pasture, and tthey will invariably go a mile to get it for their lodging. Like patent medicines it cures all diseases. It is an almost certain remedy for the fly that produces the worm in the head. If sheep can have access to a piece of burnt ground, they are sure to make it their resting place day and night. It promotes the health of sheep and does no damage to the wool. Until late in the fall, I generally keep from seven to ten hundred sheep, and have tried the above experiment, and of late years let my sheep have access to fresh burnt ground, and they are remarkably healthy.

JOHN SPICER.

A SPLENDID FARM.—Mr. J. P. Cushing, of Boston, has expended on his celebrated farm of 125 acres, at Watertown, Mass., several hundred thousand dollars. The house now building on the premises is estimated to cost $125,000. It is calculated for a princely residence, with Chinese verandahs, windows of stained glass, &c.

AUGUSTA MARKET.

TUESDAY P. M., June 20.

Cotton—Since our last publication the transactions among our cotton dealers have been heavy for the season of the year, but for the last three or four days the demand has fallen off, and a slight decline in prices has been made. We quote 4½ @ 7 cents as extremes of the market.—Little sold at either extreme.

Money—Exchange on the Northern cities, Charleston and Savannah sell from par to a small premium. Large sales of Central Bank notes have been made at from 12½ to 15 ℔ cent discount. State 6 ℔ cent Bonds are in good demand and would command 60 cents readily, and we doubt not a large amount might be sold at a few cents higher as there is much anxiety to purchase them.

COMMUNICATIONS.

MARL.

The definition of Marl is calcareous earth, and Ruffin applies the latter term to the carbonate of lime, exclusive of all other salts of lime, and of lime itself. Pure lime is never found in nature uncombined, and many of its compounds are not known to exert any influence on soils; while others, though esteemed good manures, exist in such small quantities, and so rarely occur, as to be unworthy of consideration in comparison with the carbonate of lime, which has been discovered in immense strata, hundreds of feet in depth, and miles in length, and from whose application to soils such wonderful results have been derived.

It is time that our planters were turning their serious attention to the nature of this manure. It has occupied the labor and capital of many of the most intelligent agriculturists in Virginia, since its properties have been developed by that benefactor to the planting States, Mr. EDMUND RUFFIN; and our sister State, Carolina, is under considerable excitement with the recent discovery, and favorable analysis, of large beds of marl in her eastern districts: and having Mr. Ruffin among them, to point out the mode of application, and the thousand advantages to accrue from its use, no doubt its effects will be tested wherever it is found. Although our lands are not exhausted by cultivation, and far the larger part of the State is an uncleared forest, yet our older plantations are much worn; and to save the improvements on them, to check emigration to fresher soils, and to preserve to our posterity the timber, (and avoid the extra labor,) which the opening yearly of new fields would, ere long, destroy, no effort should be spared to restore them to their original fertility. Putrescent manure, with the aid of rest, and judicious rotation of crops, is the only resort at present known, for those who are beyond the reach of calcareous earth. But to the planters in the lower section of the State, or southeast of a line through the eastern boundary of Richmond and Stewart counties, this earth may be found in abundance and probably in many places can be procured with facility, and be applied with little cost of time and labor. In Burke, particularly, nature has strewed this manure with a bountiful hand. The pile of marl at Shell Bluff would supply every plantation in the county. However, it cannot be transported by land carriage to any great distance without manifest disadvantage, and at an expense which few would be willing to incur, even if convinced of the handsome profit which such investment would ultimately yield them. But this is not necessary. This bed extends through the county, and continues through the State, as shown by the digging of wells, and has only to be searched for with a boring machine, and worked by means of a shaft. Yet a species of marl protrudes from the surface in various parts of this county, and from an analysis of a few specimens, contains about 20 per cent of the fertilizing principle; and if taken from beneath the surface, would no doubt yield a much larger proportion. It is the argillaceous marl, which if specimens of the same strength, is regarded the best, since the shells which composed it originally are entirely disintegrated, and its action upon the soil will therefore be immediate. But the object of this communication is to call attention to the subject, by stating the different effect of marl; and to furnish those who feel sufficient interest to look for and examine it, with a simple process, by which to ascertain its strength.

Marl possesses the property of modifying the texture of soils. It renders a clay soil open, loose, friable, easily worked, and penetrable below the surface by heat, air, moisture, and the enriching principles of decaying vegetable matter; and it forms with a sandy soil, a cement which closes somewhat its pores, makes it more firm, and capable of absorbing and holding water. This is proved by the fact, that clay and lime cannot be made to adhere together in the form of mortar, whereas sand and lime will form a cement. It is beneficial, therefore, to the extreme soils, and is more so to those in which sand and clay are in better proportion.

While it furnishes of itself no nutriment to vegetation, it combines with the nutritive ingredients of manure, fixes them in the soil, and only yields them to the attractive power of growing plants. Neither sun, nor rain, nor air can waste them. In a soil where clay predominates, the manure (putrescent) is absorbed and retained for a season; a portion of its elements being given to plants, while the larger part is dissipated in the air by evaporation; and when sand prevails, there is no affinity for manures, and being porous, the salts are washed through it beyond the reach of the roots of plants, and retaining no moisture, and being easily parched, the heat soon expels the gases. But the calcareous earth combines chemically with these substances, and having great affinity for moisture, and ability to absorb a large proportion of it, it is not injured by hard rains, nor materially affected by long droughts. And a happy consequence of this is, that calcareous soils never wash.

An acid soil, (known by the growth of sorrel, young pines and broom straw, and nearly all our worn soils are more or less acid,) which prevents the early decay of vegetable matter, and therefore receives no benefit from the application of manures, unless in a fermenting state, when half their principles will escape before they can be absorbed by plants, is neutralized and rendered capable of receiving and holding the products of putrefaction. And by destroying their sustenance these noxious plants are likewise destroyed.

After the intermixture of marl with the soil, by the accumulation of vegetable matter it is rendered darker in color, thus more freely absorbing the rays of the sun, and becoming warmer. The effect of this, added to the stimulating action of the marl upon plants, is to hasten them to maturity. And our cotton crop, which is now shortened by an early fall, and is developed so slowly as to require picking until very late in the season, will be ripened early, enabling a larger quantity of prime cotton to be gathered, and rapidly, so that the crop may always be housed before December.

Marl is serviceable in forming new soils on "galls" and in gullies, when mixed with putrescent matter. It will not wash, and makes the manure permanent. It serves also to deepen a soil. The marl and manure are carried down together by rain, as far as the soil will permit, which is lower than is usually ploughed. And by repeated applications of both marl and vegetable matter, the land will become fertile beyond conception.

From its power to retard somewhat the putrefaction of matter, and combine with the products of it as fast as they are evolved, it has a tendency to destroy, by seizing and retaining the miasmatic gases, (since these are generally supposed to arise from the action of heat and atmosphere on decaying matter,) and may therefore be regarded as a preservative of health wherever it is applied.

As to the permanency of its effects upon soils, Mr. Ruffin alludes to a farm in England, whose productive power, (asserted by Lord Karnes,) have increased for 120 years after the application of marl; and to another, in Virginia, which had been marled before the revolution, and whose fertility had increased, to his own knowledge, during the last 15 years. Besides, writers on agricultural chemistry place calcareous earth as an element of a good soil. It is one of the three ingredients which, united in certain

proportion, is prepared to receive manure, and support all vegetation. It is regarded as essential to a rich and proper soil, as either clay or sand, and is just as indestructible. By occasional rest, and occasional application of putrescent matter, a soil rendered calcareous artificially, will be more than double in productive capacity in 10 years, and quadrupled in 20 years; and if the theory is correct, which I do not doubt, but which practice has not fully established, because sufficient time has not elapsed to test it effectually, there will scarcely be a limit to its increasing fertility. But I cannot intrude upon your space to enlarge upon the subject. At a future time I may briefly state the mode of applying marl, and the character of those soils upon which its effects will be earliest and strongest.

To Analyse Marl.—Take a specimen, dry it perfectly in a shovel over the fire, pulverize it thoroughly in a mortar, and weigh accurately 50 grains of it. Take next a retort with as open a mouth as practicable, put into it about 200 grains of muriatic acid, diluted if you please with once or twice its bulk of water, place retort and contents in the scales, balance them and note the weight. Next, pore carefully the 50 grains of marl into the retort; give time for the carbonic acid gas, which rises with effervescence in a white vapor, to escape. When the effervescence ceases, and the vapor has entirely passed off, which you can aid by blowing, balance the scales again ond note the difference of weight. Say, for example, that this difference is 20 grains, then, knowing that every 100 grains of carbonate of lime contains 44 grains of carbonic acid gas and 56 grains of lime, and having taken 50 grains of marl, we have the following proportion:

If 22 grains of carb. acid gas are found in 50 grains of carb. of lime, how many are 20 grains carb. acid gas (which we supposed escaped from the retort,) found? Answer, 45 grains of carb. of lime: or,

22:50::20:45—which last term is the quantity of carbonate of lime in a 100 grains of the marl analysed. A BURKE FARMER.

JEFFERSON HALL, GREEN CO., June 15, 1843.

Messrs. JONES—The enclosed recipe, which is doubtless a good one, and which is simple and easily procured, I wish published in the Southern Cultivator.

Yours, respectfully, A. G.

"CURE FOR THE BOTS.—The editor of the Baton Rouge Gazette states, that he is informed by gentlemen who know, that strong tea, made of common garden sage is one of the most effectual remedies for bots in horses ever discovered. Also, a branch of sage chopped into the feed of horses once a week, will prevent the bots altogether.

When your horse is taken ill of the bots, give about a quart of strong sage tea, and he will recover in a few minutes.

The above remedy is simple enough in all conscience, and has this to recommend it—if it should do no good, it can do no harm—and being innocent in itself, is, we should think, worthy of trial."

CURE FOR BOTS IN HORSES.

Make a strong decoction of tansey tea, bruise and press out the juice, and drench with a quart at a time. It is said by a very knowing old lady of Morgan county, to be the very best of remedies. It is also stated, on good authority, that the grub, dropped in a strong tea of the above plant, will immediately die.

Green County, June 19.

WILKES COUNTY GA., June 24, 1843.

Messrs. EDITORS.—I will comply with your request for all your subscribers to communicate their experience to you, or at least a part of it. As I am not accustomed to writing I hope you will correct all mistakes.

The subject to which I would call the attention of farmers, is one of great importance to them—it is.

THE CULTIVATION OF THE GRASSES.

There is very little attention paid to this subject in this county, and very little in the State. I do not know of a single farmer in this county who sows any kind of grass seed—they say there is plenty to cut up now without planting more. Now I do not know of one good reason for not planting grass seed. We can have as good clover here as at the north, and there are a great number of grasses which are natives. I have had grass growing in a square in my garden, three feet high, and which made as good hay as I ever saw. It is the kind called here "crow's foot."

It seems as if our farmers would rather have their cattle poor and starving, than to be at the trouble of sowing grass to make hay for them, when there is nothing for them to eat in the fields. Now this is all wrong. If they would build good shelters for their cattle, and provide enough for them to eat, they would find it more to their profit. Cattle when sheltered do not eat as much as when kept in the cold blast of winter; where they get on the sunny side of a fence and shiver as if almost frozen. Another thing, cows give more milk when kept under a warm shelter, and do not eat as much by one third.—I asked a farmer last winter, how his cattle stood it. He replied, "they could all get up without help and that was all." There is another thing in which our farmers are at fault—it is, they keep too many cattle. If they would keep fewer and keep them well, they would be gainers by it.

It is a matter of rejoicing that the people are waking up to the importance of improving their land and keeping better stock. I will not encroach on your valuable paper farther. If you think the above worthy of a place, give it. You may hear from me again.

I remain your friend, A. O.

FRUIT STAINS.—The fumes of brimstone will remove fruit stains and iron mould fram linen and cotton. Moisten the part stained with cold water, then hold it over the smoke of burning brimstone till the stain disappears.

WOUNDS AND BRUISES ON HORSES.—Take one quarter of a pound of saltpetre, half a pint of vinegar, half a pint of spirits of turpentine, put them together in a bottle, and shake up before using. Apply it to the wound with a feather, three times a day.

TRANSACTIONS OF THE NEW YORK AGRICULTURAL SOCIETY.

We are indebted, says the editor of the Southern Planter, to the politeness of Mr. Luther Tucker, the Secretary, for the second volume of the Transactions of the New York State Agricultural Society. As in the last volume, so in this, we meet with matter of great ability and of general and absorbing interest. Amongst other things, we find two prize essays, from the pen of Willis Gaylord, Esq., occupying sixty pages, every word of which we should be glad to transfer to our columns, if the nature of our work permitted. As it is, we must be content with making brief extracts from such portions of these essays as we deem most interesting to our readers. The first essay is on

THE PREPARATION AND USE OF MANURES.

After examining the nature and constitution of plants, Mr. Gaylord remarks, "In the preparation of manures, the principal object to be aimed at must be to supply materials for the formation of carbon and ammonia; and these are found in the greatest abundance in dead or decomposed animal and vegetable matter." He then proceeds to consider separately the different kinds of manures, under appropriate heads, and first of

ANIMAL MANURES.

He quotes a late British writer on agriculture, who says, "If cattle repay their food and the expense and risk attending their keeping, the manure is sufficient profit. Even with a moderate loss, they must be kept when manure cannot be purchased. Manure is to a farm what daily food is to an animal; it must be procured at any sacrifice." Mr. Gaylord thinks, that to such crops as corn, potatoes, &c. that do not require forcing in the early part of their growth, but demand nutriment at a late period of their vegetation, to perfect their seeds or roots, long manure may well be applied in the spring; being well covered, fermentation will not take place until the gases, which are eliminated in that process, will be retained by the earthy covering, and appropriated by the roots of the plants. To preserve manure for such purposes, he thinks, that the usual plan of incorporating the drippings of the cattle with the usual litter of the farm yard, during the winter months when the absence of heat prevents decomposition, is fully sufficient; but for other crops, as turneps, beets and carrots, where the influence of manure is required to be felt at once, in order to push them forward at the first start beyond the reach of insects, he thinks the vegetable matter should be reduced to a state of perfect decomposition, before its application. Whenever this process takes place, the vegetable matter should be protected and covered, as in the compost heap, with alternate layers of sod, earth from ditches, ponds, &c. which may absorb the drainings of the manure above, and arrest the ascent of the gases from the manure below. He says, "the more solid such deposits of manure are made, the more slow will the fermentation be. Should the dung in the heaps be too slow in fermentation, it may be hastened by opening the piles, or still better, by making holes in the top into which the wash of the yards and the urine of the stable may be poured."

If Mr. Gaylord is correct in supposing that no loss occurs during the winter months in the farm-yard manure, his plan of hauling it out and covering it up at that season when the heat generates decomposition, is highly to be recommended; because it saves all the labor of the compost heap during the winter season. But, in our southern climate, at least, we imagine that the loss, even during the winter, from evaporation and solution, would more than justify the labor of daily collection and addition to the compost heap. In addition to the earth and sods, which are mere mechanical retainers, we

do not doubt that valuable chemical agents, as gypsum, salt, &c. may be added, whereby desirable combinations with the gases, &c. liberated in the process of decomposition, may be obtained. Upon this portion of the subject the science of chemistry is one day destined to shed most valuable light.

Upon the subject of

GREEN CROPS,

Mr. Gaylord remarks, "For a plant to enrich exhausted soils, affording as it does both top and roots to a large extent, there is no plant equal to *clover;* and particularly where it is necessary or desirable to have the green crop fed off by animals. I prefer letting the clover grow until nearly or quite in blossom, and then turning sheep upon it. They will eat much of it and fatten rapidly; but they will trample down more, and this, mixed with their dung, forms in its decay a most efficient top dressing; and repeated for two or three years, forms an admirable preparation of the soil for wheat or other grains. When a crop is cultivated to be ploughed in, it should be done at the time when the plants contain the greatest quantity of nutritive matter, and have least exhausted the soil in which they are growing. This, in most cases, will be when the plants have come fully into flower. At an earlier period there may be as much weight, but a larger portion of it will be mere water; and, if allowed to stand much later, the soluble matter is lost in the seed, and the ligneous part of the stem becomes more difficult of decomposition Buckwheat is a good plant for a green manure; its growth is rapid, and gives a great weight per acre, and two crops may be ploughed under in a year. The best way of ploughing in such green crops, is to pass a heavy roller over them, which lays the plants close to the ground, and greatly facilitates covering them with the plough. It is believed that corn, sown broadcast, and when just showing its tassels, cut and covered by the plough, would be one of the best crops that could be chosen for this purpose. A man or boy, in this case, would be required to follow the plough, to place the corn in the furrow for covering, at the next passage of the plough. Taken at this time, corn abounds in nutritive matter, and could scarcely fail af proving a first rate fertilizer of the soil.

Mr. Gaylord thinks that wherever other vegetable matter can be had, fallen LEAVES will not pay the expense of gathering.

PEAT, SWAMP AND POND MUD,

he esteems very highly, but these substances applied in their natural state are almost inoperative, as compared with stable manure. To enable it to give out the ammonia, with which it abounds, peat or swamp muck must be fermented, and it is for want of this process that it is so little esteemed, in general. To bring it to this state, we are recommended to compost it with half its bulk of stable dung, which it is asserted will form a heap equal in fertilizing properties to three times the quantity of dung employed.

Poudrette, urate, guano and other peculiar manures are brought under our notice in order, but passing over these we come to the more general one of

LIME.

Upon this subject our author remarks, "It appears as the result of experience, that lime produces the best effect on what are called stiff loams, or loams inclining to clay, and in which a good proportion of decayed organic matter is found.

"It is found, too that it operates more favorably on soils natural to oak and its kindred trees, such as walnut, poplar, &c. than on those where the beech, elm and maple constitute the principle timber. It is singular that the richest limestone lands, as they are called from being based on this rock, are frequently those on which heavy dressings of lime operate like a charm.

"If used as a top dressing, lime is usually applied to the sod in the fall; but the practice most approved, is to lime the corn ground in the spring, on the inverted sod. Manure is applied to the wheat crop after lime. The quantity of lime used varies much. There is no doubt it has sometimes been used in excessive quantities; and when used on soils nearly destitute of vegetable matter, can produce no good effect.—On a medium soil, fifty bushels per acre may be considered an abundant dressing; but three or four times that quantity is sometimes used. The best method of using lime, is to take it from the kiln, unslacked, and deposite it in heaps in the field where it is to be used, not more than three or four bushels in a place; and either slack it by pouring water over it, or, which is better, by covering each pile with earth, and letting them slack by the moisture thus furnished. When sufficiently fine, the earth and the lime are mixed by shovelling over, and the mass is then scattered over the land to be dressed. The soil should be well harrowed after the application, to incorporate it more completely with the surface earth."

SALT

is very highly recommended. "It appears that salt in small proportions, promotes the decomposition of animal and vegetable substances; that it destroys vermin and kills weeds; that it is a direct constituent of some plants, and therefore necessary to their perfection; that all cultivated plants of marine origin contain it, asparagus, for instance; and that all such succeed better when watered with salt water, than when deprived of it; that salt preserves vegetables from injury by sudden transitions in temperature, salted soils not freezing as rapidly as those to which salt has not been applied; and that it renders the earth more capable of absorbing the moisture of the atmosphere. When salt is applied as a manure, it may be used in quantities from six to fifteen bushels per acre; although some have gone as high as fifty bushels. Farmers, however, should be cautious how they venture on excessive doses, as an extravagant one could scarcely fail of being fatal to any crop.

"Salt and lime, artificially mixed as a manure, promises to be a valuable aid to the farmer in those positions where the soil abounds with insoluble silicates or geine, and where other manures necessary to produce decomposition or fermentation are not at hand. Professor Johnston recommends a mixture of two parts of lime and one part of salt, the mixture to remain incorporated in a shady place, or covered with sods two or three months before using. Salt and lime should not be used immediately after mixing, as bad results are apt to ensue; but after being well mixed in a dry state and lying as directed, it may be applied at the rate of from thirty to sixty bushels per acre, either before or at the time of sowing.

"Dr Dana directs to take one bushel of salt and two bushels of lime; to make the salt into strong brine, and with it slack the lime. Mix both well together, and let them remain ten days; then let them be well mixed with three cords of peat, shoveled well over for about six weeks, when it may be used. A quantity of salt sufficient to destroy all vegetation, may be applied to a soil with safety when a few months are to elapse before the crop is to be put on; as the chemical changes which take place, partially neutralize its effect during this time. A small quantity mixed with the soil in each hill of corn, has been found to protect it from the wire worm and the cut worm, indeed there is no substance that insects of all kinds more dread than salt. It is probable, therefore, that further experiments will show that not the least value of salt is to be found in its preventive properties against these depredators. Mixed with soot, salt acts with great power on roots."

We know how objectionable long articles are in general, and have endeavored to compress the *gist* of this valuable essay into a few pages. The subject is in its nature extensive, and we fear we have done injustice to Mr. Gaylord in our abridgement. Indeed, properly considered the essay, long as it is, is nothing but a series of condensed remarks upon a variety of subjects, all coming under the general head of "manures."

AMERICAN MANUFACTURED SILKS.

The Baltimore Patriot of the 22d ult. says:—Mr. John W. Gill, proprietor of a Silk Manufactory at Mount Pleasant, Jefferson county, Ohio, has been exhibiting at Barnum's City Hotel, for some days past, a variety of very handsome and substantial specimens of American Silks, manufactured entirely by himself. They consist of gloves, cravats, handkerchiefs, stockings, scarfs, pieces in the web, for ladies' dresses, of different colors, besides numerous other articles, all of which have an admirable texture, and appear to be of a highly durable quality.—Mr. G. states that his enterprise has thus far proved successful, even beyond his most sanguine expectations. Besides the factory, which employs about fifty hands on an average, he has a large Mulberry grove and an extensive cocoonery, whereby he is enabled to raise a considerable portion of the worms that supply the raw material. It is several years since this enterprise was undertaken by Mr. Gill, and at present he has invested in it about $30,000, which yields, as he states, a very handsome equivalent. Having given much attention to the business in its various branches, he has also had an opportunity of discovering the best manner of cultivating the worm. to accomplish which a ventillating apparatus has been invented by him, to facilitate the worm in feeding, found to be of great service. It is simple in construction, saves much labor, and is accounted a highly valuable improvement.

The success thus secured by the unremitting perseverance of this gentleman, in a comparatively new section of our country, goes far to show that the manufacture of silks in America, is destined, at some future period, to assume an importance commensurate with the laudable ambition of those who gave to it the first impulse. Facts are the strongest arguments, and we think those noticed here, are conclusive proofs that much can and will yet be accomplished in this country in reference to the manufacture of silks, and the cultivation of the silk worm.

PRESERVING EGGS.—It would be quite a valuable discovery to farmers in the neighborhood of a large market, as well as to household economy, if a cheap and easy method of preserving eggs could be practised, whereby the price would be more equalized through the various seasons of the year. Reaumer, the inventor of the thermometer which bears his name, tried many experiments for this purpose, and found that the cheapest and most effectual method was to apply oil or grease, with which they were rubbed, or into which they were dipped. He found that they were preserved quite as well by the thinnest layer of fat, as by the thickest coating, so that every part of the shell, (which is porous and admits air,) was covered. All sort of fat, grease or oil, he found well adapted to preserve eggs, and kept them in this way, he says, for nine months, as fresh and good as the day they were laid. Will some of our readers try a few dozen in this way, and let us know the result.—*Newburyport Herald.*

PRESERVING SCYTHES, &C. FROM RUST.—To preserve scythes, sickles, reaping hooks, and other steel tools from rust after the season for using them, wipe them clean and dry, and hold them before the fire and keep drawing them backwards and forwards until warm enough to melt wax; then take some beeswax and rub it all over. A half-penny worth of wax will be sufficient for a sythe. Then put it in a dry place, but not warm; it needs no other covering. The usual method is to wrap a hay-band round; but in winter time this naturally contracts moisture, or the damp air strikes in betwixt the folds of the hay-band.—*Farmers' Magazine.*

JUDGE O'NEALL'S ADDRESS,

Delivered before the South Carolina State Agricultural Society, December 29, 1842.

FELLOW MEMBERS:—Circumstances beyond my control have prevented me from bestowing that preparation upon the address, with which you charged me, which I desired to give it, and which it merited to receive. Rather, however, than wholly fail in the discharge of a duty assigned me, the work of a few hours, naked and unadorned, is presented to you.

In approaching the consideration of agriculture, the mind naturally turns back and asks, what is its origin? It is coeval with man himself! His first position of primeval innocence and happiness was to dress and keep the garden of Eden. In this is manifested the divine appointment, that in tilling the earth is to be found man's best and happiest employment.

When man was tempted, fell and was banished from the garden, the curse of God was not one of unmitigated severity. There was not only the hope of happiness beyond the grave, to console the erring father of men, but also an assurance of an abundance to sustain this present life, to be obtained by labor well and properly applied. "*In the sweat of thy face shalt thou eat bread,*" was the announcement of his future destiny, and that of his mate; and when it has been well and faithfully obeyed, by industrious occupation, it has not only blessed individuals, *but nations.* Indeed, in all ages of the world, national prosperity has depended upon the state of agriculture. Where it has flourished, every thing else has also flourished. The palmiest days of the eastern world, were those when her soil was cultivated like a garden; when Egypt could point to her whole surface, as a field of waving corn, irrigated by the waters of the Nile; when Syria could look upon her plains, teeming with luxuriance, as her terraced mountains, crowned with the labors of man; and when Italy could sit down in the midst of her vineyards, and her fields, and from her cornucopia pour their rich reward into the lap of the laboring husbandman.

It is not, however, its only general benefit that it contributes to national prosperity. I have no hesitation in saying that it is the only rock on which a nation can build, in the hope of more than an ephemeral existence. Here reasoning is unimportant, *let facts speak.*

Where are the great merchant cities of Tyre and Sidon? They are rocks on which fishermen dry their nets! Where is Babylon? She has perished! Where is Palmyra? Covered, with all her glories, in the sands of the desert! Where is Thebes, with her hundred gates? She "was and is not," is the answer of history.—Egypt, the victim of tyranny and misrule under her Coptic, Grecian, Roman and Mohommedan rulers, still knows her "years of plenty;" and by her agricultural riches, has enabled her tyrant to breast the proud domination of his own master.

Syria, trodden under foot by men who are more merciless than the beasts of the forest, can still point to spots of her soil, which know the husbandman's care and culture, and which bring forth abundantly; and to her mountain fastnesses for that free spirit which was born, nurtured and bred in the pure air of the cultivated fields, and which, in its manhood's prime, is yet to burst, as if they were of tow, the chains of Turkish slavery, and to clothe her again with that luxuriance which denoted her as a "land flowing with milk and honey."

China, with her millions upon millions, on land and water, the oldest nation of the world, has been alone sustained by her agriculture; for her commerce is only the privilege of a few, and has neither fed nor clothed the great body of her people. When, at this moment, England is thundering at her gates for the purpose of compelling her to pursue *an unholy traffic,* her only safety is in the immense masses of her people, and their capability of providing food for themselves, and thus overcoming, by patient endurance, *a cruel and unjust war.*

Continental Europe, ravaged as she has been by the armies of England, France, Austria, Rrussia and Prussia, points to her laboring peasantry, and in the language of Goldsmith, exclaims,

"Princes and lords may flourish and may fade,
A breath can make them, and a breath has made;
But a bold peasantry, a nation's pride,
When once destroyed, can never be supplied."

Her agriculture has sustained her tottering thrones, and her people cut down and apparently annihilated, have sprung up again, like the armed men of Cadmus, at her bidding. But her merchant cities have not been equally successful. Venice, stript of her gorgeous robes, is no longer the bride of the Adriatic! She has not utterly perished, like Tadmor of the wilderness, or Bozrah; but her canals and her storehouses are no longer thronged and filled by the trade of the world.

England, on whose dominions the sun never sets, has attained her proud eminence more by her agricultural resources than in any other way. True, her commerce has whitened every sea, and every breeze has borne to her untold treasure, still the results of almost every foot of her surface, tilled by experienced and skilful agriculturists, have furnished the means which equipped and sent forth her gallant barques to every clime. This too, has been the case when her agriculture has been fettered by unwise legislation, and when that unholy principle which devotes the many to the few has been enforced.

In America, the forest, the soil, and the luxuriant productions which a little labor can secure, all unite in recommending agriculture to us as our first, greatest and best pursuit; yet how little heed has heretofore been paid to skilful husbandry? Of late, it is true, so much has been said, and so well said, to recommend it to the respectful consideration of every one, that little remains, which can be considered new or interesting. Still, notwithstanding this, agriculture, with us in South Carolina, is a neglected science, with few real followers, and with scarcely one capable of teaching its simplest elements. Other sciences are crowded and traced out and pursued to their most legitimate results. The earth, in the mean time, like an indulgent mother, is treated with constant neglect. She flings her treasures into the laps of improvident husbandry, which in return leaves her bosom to be furrowed deeper and deeper, by the rains and frosts and snows of winter. In a few years, she is clothed with the sere and yellow garments of sterility, and the occupant seeks some other genial spot on which he can plant, and from which he can gather abundance, until exhausted nature sinks into repose and barrenness. This is no fancy sketch, it is the result of practical husbandry, as carried out in the cotton planting States, and especially in South Carolina. Is this the necessary result? Science, knowledge, practical skill, enlightened as it should be, answer no! The cultivation of the earth, with rotations of crops, and intervals of rest, is just as practicable in the cotton growing States, as it is elsewhere. Let us restrain ourselves and recollect, that less land, *well planted, well manured, and well cultivated,* will make larger results, than larger quantities, *badly planted, unaided by manure, and imperfectly cultivated.* Cotton land, as level as can be selected, can be more easily preserved. If none other than rolling land can be procured, then horizontal plowing and ditching will do much to save it.—But that policy, which leaves the cotton beds and furrows to stand during the winter, will soon prove how disastrous it is, by precipitating the rich loam of the hill sides into the valleys below. How much wisdom would there be in ploughing against and around the whole surface of a cotton field, as soon as the crop was gathered. The soil would thus be saved, and the land would be in better heart for the succeeding crop. Some of the formerly rich hills of the Catawba and Broad River, are now seamed with gullies, and surmounted with irremediable barrenness. The traveller would ask how has this happened? The answer is before us, in the cultivation which our ancestors followed, and which we are still pursuing.

In the level lands of the middle and lower country, there is no excuse for the sterility which abounds. Nature has here lavishly provided for the wants of man, in the teeming luxuriance which greets his efforts, but he forgets that the earth, like man, may become worn out, by being over-tasked. The remedy is at hand, *manure;* and in most sections, marl abounds; it is only necessary to seek and apply it, and the earth exchanges old age and sterility for youth and abundance. In the upper districts, this last advantage, so far as we have been able to examine, does not exist; still, in many parts of the country, inexhaustible beds of limestone are found. In Laurens district, on Rabun's Creek, nine miles southwest of Laurens C. H. on the plantation of John S. James, Esq., is a most extensive quarry of fine limestone, of very much the same character with that at the Limestone Springs, in Spartanburg district. It is in a fine section for agriculture. The lands are rich loam or red clay. The lime in their very midst will make them richer and more productive than they ever were. For wheat, the land of that neighborhood is as well, if not better, adapted than any with which I am acquainted, and if the lime, which is so accessible to their owners, was well applied, it would make them produce some thirty, some sixty, and some an hundred fold. The same vein running from northeast to southwest, is found at the Limestone Springs, and through the whole region from Broad River to King's Mountain. What fertility might be given to the thin and comparatively barren soils of this whole region by the judicious application of the mineral treasure in her bosom! In the hands of New England enterprize, it would be as a garden. Why not so in ours? Simply because necessity has not, as yet, taught us the value of assisting nature in her attempts to bless us.

That there is a better prospect ahead, is evidenced by the great interest beginning to be felt by *farmers* in Agricultural Societies. They are no longer left to be managed by lawyers, doctors, clergymen and educated men *alone.*—The tillers of the earth, *that noble yeomanry,* who earn their daily bread by the sweat of their brows, are members, and are bringing to theory and *book farming* all the aids of practical husbandry. The two united are what we want.—In the exchange of ideas thus with one another and the correction of faults by experience, we may hope that every year is doing something to benefit the State.

One great object to be attained is, to arrest and prevent that disastrous spirit of migration which, in twelve years, has carried from us one third of our wealth and population. Like the discoverers of America, "gold, more gold," has been the unceasing demand of our people.—When South Carolina yielded nearly $300 for every laboror, still it was not enough; and like the Indian, pointing his Spanish conquerers to the interior for the richer mines, so cupidity pointed our people to the richer fields and prairies of the southwest, as more and more productive. There they expected to find the *el dorado,* but the chase has been in vain; and the conviction is beginning to roll back upon us, that we need no better country than our own cherished home, our own, our native State, South Carolina, if we will bring to her service all the aids of enterprize, industry and intelligence which we possess. Contemplate the scene around us, and we may well ask, is there, in these times of disaster, trial and difficulty, any portion of the world better off than South Carolina? None! Here distress is partial; and in the other States of the Union, (except North Carolina,) it is universal and overwhelming.—How is it so? South Carolina has neglected her agricultural resources; crippled herself in many vain and visionary undertakings; still she had but "to arise and shake herself as she was wont," and all was well. Whence this comparative prosperity? The answer is, *our faith*

has been kept; our credit has been preserved; our cotton bags and our barrels of rice have annually met the demands upon us! This comparatively happy and blessed condition demands unceasing gratitude to the Great Giver of every good, who has blessed us with plenty, and put it into the hearts of our rulers to rule with honesty and govern with wisdom! This has been especially and signally the case with your moneyed institutions, *your banks.* While in all other quarters explosion has followed explosion, fraud has succeeded fraud, *here* bills have maintained a specie value, and no one has supposed that mismanagement or fraud mingled in the management of a single bank in South Carolina. That much of our prosperity is to be ascribed to this fact, cannot be denied; and if South Carolinians ought to be prouder of one thing than another, it is that her sons have passed the ordeal of bank temptations, unsuspected, uncorrupted.

This contemplation, this reflection, this comparison of ourselves with our neighbors, is surely enough to prevent the further spread of the spirit of emigration. Let each citizen of the State come to this conclusion, "South Carolina is my home, I will do her and myself all the good I can," and he will find, in the language of an early settler of the State, "South Carolina is the garden spot of the world." This may be said to be an extravagant view of the matter.—Test it in any way you please, and it will be found to have no romance in it.

There is an old proverb, that "a rolling stone gathers no moss." Just so it is with the emigrant. He is rolling on to his fancied treasury of abundance, but all is nakedness around him, and in his track. He may at last rest, and gather together, in a country to which he is a stranger, great abundance. He still looks back to the land out of which he came, and remembers it with regret. He who is content to remain in permanent and useful fixtures, establishes his comfort, and in constant attention to his land, in crops, and by the judicious application of manures, overcomes even barrenness, and in the increased product, he finds *at home* that abundance which the richer fields of the southwest promised him. That this could be proved by many instances, I may refer to each member's knowledge of the events which have transpired around him within the lost twelve years.

Are not, fellow members, these considerations, to which your attention has been turned, enough to make you redouble the interest which, as agriculturists, you feel in the State in which you live? Improvement is our motive and object. Therefore it is we meet *here* annually, that by a free intercourse from the mountains to the seaboard we may gather the lessons of experience, and bind them upon our hearts, and go forth to test them in the labors of the coming year. In this way, much good is done, and we may begin soon to flatter ourselves that we will have something like an agriculture of our own.

This, however, demands what we have not, in all parts of the State, *an educated class of husbandmen.* When I say educated, I do not mean *"book-learned farmers;"* I mean *men thoroughly trained to their business.* The great fault of education in South Carolina is, *that it has no particular application.* The clergyman, the lawyer, the physician, the merchant, the mechanic, and the farmer, are all educated alike. The mere statement of the fact shows the defect.—How is it to be remedied? We have not schools arranged for every department of life, and perhaps such are not always desirable. But with suitable attention on the part of parents and guardians, education might be so directed as to fit a man for his business, instead of making him a prodigy of learning, *without one particle of common sense.* The future farmer and planter needs but the careful and judicious training of home, to be prepared for his station. In early life, in the intervals of his scholastic education, if his mind was turned to the acquisition of useful knowledge in the management of the farm, and his hands were trained to the use of tools, he would insensibly become fit to be the head of a well ordered plantation. The vices and diseases resulting from idleness, would be thus prevented, and the young men of South Carolina, instead of growing up in the shade, and liable to be withered by the blighting influence of a burning summer's sun, would grow up with nerves strung by moderate toil, and be men capable of facing and performing their duty.—This preparation will not unfit the young mind for the acquisition of knowledge; indeed, it will increase its capabilities. Exercise, with an object to be attained, blesses with the *"mens sana in sano corpore."* To such an one, education will not open out her blooms in vain: he will pass from flower to flower, and from each extract that which is good or pleasant, and return to his post in society, laden with the rich and varied treasures of *useful learning.*

We need, too, the lessons of patience.—Promptness is a part of our Southern character; we must add to it endurance, before we can succeed as agriculturists. Whatever is attempted should be thoroughly tried before it is abandoned. Many of the schemes to which our attention has been of late turned, are no doubt mere humbugs. Still this is to be said—every thing may be called a humbug until its utility is tested. It is the part of wisdom to try every thing which bids fair to profit us; and one trial perhaps is never enough---it is at least entitled to an Irishman's privilege, of being twice heard. This is particularly the case when we are looking around, on the right hand and on the left, for the substitute for our great failing staple, cotton. Many things must be tried; but it will be in vain to expect any to take its place at once.

Indeed, it seems to me, that there is one remedy, and only one, for the state of things resulting from the low prices of cotton; it consists of economy at home and abroad. If we could bring ourselves down to the standard which the present price of cotton presents, all would soon be well. Buy neither pork, mules nor horses. Let these be the product of the farm, and one branch of our present difficulties will be cut off. Carry this spirit of retrenchment into the household, and let home furnish all the usual supplies of clothing for the laborers, and hard times will begin to be good times. Real independence, that which is above want, will occupy every farm. I often go back to the period from 1808 to 1815, when legislators were not ashamed to meet in homespun, when ladies vied with each other, not in the luxury of foreign dresses, but in those made at home, and ask when was South Carolina more happy? Never, within my knowledge. Does this time demand similar sacrifices? Your own sense of the necessity around you must answer the question.

Of one thing there is no doubt, the capabilities of the State are hardly known. Her agriculture is in its infancy. She is just pluming herself for a loftier flight than any she has ever before attempted. Our fields are to be cultivated with more skill; better and more numerous stocks are to be reared; South Carolina is to become less a planting and more a farming State. That this will add to her greatness and her happiness cannot be denied. In this effort she has, it is true, one peculiar difficulty to encounter, in the carelessness of her operatives. Still, our slaves are capable of more, much more, than we have hitherto had credit for. It is only necessary that they should be taught habits of regularity, economy and thrift, to make them the most effective laborers in the world. This is what we are attempting. Let the owner be resident, as far as practicable, on his plantation; and let him understand well that which he is about carrying out. Let his slaves be taught that his interests are their interests. Begin with small things, and teach them the necessity of attention. For instance, teach them the absolute necessity of shutting a gate, or putting up a rail when out of its place; of carefully feeding and watering the stock under their care; and there will not be much complaint about *negro carelessness.* When this much is accomplished, the whole difficulty is overcome, and there is nothing to prevent a South Carolina farmer from competing with any one in any of the adjoining States. To my brother-farmers, intelligent and experienced as you are, I need not add, you cannot succeed with negroes, as operatives, as you desire to do, *unless you feed and clothe well.*—Make them contented, and then "Massa" will be, as he ought to be, the whole world to them.

In our climate, health is supposed to be uncertain, and that this fact will always stand very much in the way of agricultural improvement. The difficulty exists, and in the lower part of the State is, beyond all doubt, a great obstacle to improvement. Still, it is not insuperable, *even there.* For Nature, kind and provident as she always is, has provided pine lands in the neighborhood of the rich swamp lands, where the owners can reside in comparative safety. In the interior of late years, we have been scourged with disease, even to the foot of our majestic mountains. That it has visited us as a pestilence, and as a chastisement for our sins, is beyond all doubt, the true Christian view of the matter. Still it is our duty, as far as we have the knowledge or the means, to remove the secondary causes. In a country like ours, undergoing the process of having the forest annually cleared away, it is to be expected that many causes of disease will thus be produced. The hill-sides cleared, and the ravines filled up with the timber cut down from above, and afterwards with the alluvial from the cultivated hill sides, cannot do otherwise than produce disease. So, too, where streams or springs are choked or covered up, the neighborhood must expect the fall fever. These causes may easily be removed, by ditching, draining and cutting away the drifts. But the annual decomposition of the leaves in oak and hickory land, with the decaying timber allowed to lie and rot upon the ground, will produce disease, especially in wet summers. The remedy for this was suggested by the intelligent foreman of the Grand Jury of York District, at the last Fall Term, (Mr. John Springs,) *"burn the woods."* Let this be done early in the season, before the sap begins to run, and no injury will occur to the timber. But some suppose the soil will be injured; intelligent, observing men, on the contrary, believe that the ashes of the leaves are worth more to the land than their natural decomposition; and, so far as I have had experience, I am satisfied their views are correct. If, however, there was a doubt about it, health is of too much importance to be weighed against such a consideration. In York District, during the last season, from 300 to 400 of the inhabitants were gathered to their fathers. What an awful mortality! How important, if practicable, to counteract it, and prevent its recurrence! A country visited annually with fever never can improve in that ratio in which it would without it. It is our duty, therefore, to make every effort we can to restore the State to health.

Much will depend upon habits of regularity in every thing; and temperance in eating and drinking is essential to health. To farmers, men who are exposed to the vertical rays of our summer's sun, this advice cannot be too often repeated. Good, pure cold water, I regard as essential to the health of laborers. If the water which they drink is impure, it is in vain to expect health; with a little, very little attention, this first and best gift to man can in all places be secured.

At this time, much depends upon properly developing the resources of every district. If marl can be found above Orangeburgh, what incalculable benefits would flow from the discovery to every place where it might be, or to which it might be accessible. So, too, if the vein of limestone which is seen in York, Spartanburgh and Laurens, could be traced and made available throughout its whole course, great good might result therefrom. So, too, a careful analysis of our soils, and the suggestions of science, pointing out that which was

wanting to restore or increase their fertility, would be a great desideratum. In many sections minerals abound; their knowledge and proper classification would contribute much to the wealth of the State. Paints, asbestos, fossils, and clays of various kinds, and of great value, are known to exist in the State, and still no one can say, with certainty, any thing about them.

An agricultural survey of the State, in some way, ought to be obtained. Whether the State should make an appropriation for this subject, is a matter which belongs appropriately to her representatives, now assembled, and not to us. One thing is, however, certain, a small sum of money could not be better and more appropriately applied. It might be, that the intelligent gentleman who fills the chemical chair of the South Carolina College, could be induced to devote his vacations, for a few years, to this purpose. Nothing, I am sure, could place him higher in the good opinion of the people, or would confer a more lasting favor on South Carolina, than such a service.

In conclusion, fellow members, permit me to say, that the work in which we have embarked is no evanescent affair. It is for life! For agriculture is that upon which we all depend for subsistence. To it we often look as so common a thing as not to deserve much heed. But it is of far greater importance than any thing else in which we are engaged. Every thing else may be dispensed with; but this and life are so intimately blended, that together they live or together they perish. With one mind and one spirit, let us press the work in which we are engaged. In the language of empiricism, it may do us good, it can do us no harm. It may make us all better farmers, better citizens; but better patriots I hope none of us require to be. To our country, in one way or another, we are all devoted; and to our country's welfare let us all cheerfully contribute every thing we can to increase and bless her!

Columbia Planter.

BOMMER'S MANURE.

We know of no invention that has excited more curiosity than Mr. Bommer's new process of making manure. We have had hundreds of applications upon the subject, and we have returned but one answer to all the applicants, viz: "We have no personal knowledge upon the subject, but we have put the matter in the hands of a gentleman in this neighborhood, to be thoroughly tested by him, and his report, whether for good or for evil, will be published in the July number of the Planter." This report, which we are happy to find is of the most satisfactory character, is contained in the letter below from Mr. Woodfin. It is unnecessary for us to say any thing in this community of the standing and respectability of this gentleman; to those to whom he is unknown we will say, that we selected him as one of those individuals whose testimony would go as far as any body's. Mr. Woodfin is also known to most of the readers of agricultural papers for his skill and science in agricultural chemistry, to which, of late years, he has devoted much of his attention.

Southern Planter.

MR. CHARLES T. BOTTS:

Dear Sir—Having been requested by you to give a candid statement of my opinion of Bommer's patent method of making manure, for publication in your July number of the Planter, I will now with much pleasure proceed to say all I know about it.

On the 13th of May at night, I finished the preparation of a heap, according to this method, composed chiefly of dry wheat-straw, to which I added a small quantity of coarse unfermented stable litter, which was also, mostly wheat-straw, and proceeded to treat it according to the directions laid down in his pamphlet. On the 18th day after the heap was constructed, it was opened in the presence of a number of farmers, and other gentlemen feeling an interest in the matter. It was found not to be entirely decomposed, but in a high state of fermentation, which gave evidence that entire decomposition of the materials would very soon be the result: in order to facilitate it, however, I gave it another watering with the lees, which has effected the complete decomposition of the whole mass.—According to Mr. Bommer's method, entire decomposition should have been effected in fifteen days, and I have no doubt such would have been the result, if it had been conducted with more skill; up to the tenth day, I had succeeded in producing a very high degree of heat; on that day I gave it a very copious watering, thereby adulterating the lees too much, which caused the fermentation to subside in a measure. If the third watering had been properly made, with the lees in sufficient strength, I have no doubt the result would have been more satisfactory.—As it is, I have succeeded in thirty days, in accomplishing that which I could not, by any method known to me, have accomplished in six months. I have never used any of this manure, this being the only heap I have made, I cannot, therefore speak of its effect on vegetation; from its appearance, however, and my knowledge of the materials used in its manufacture, I should consider it of far greater value than the best stable manure, made in the usual way; I would not now exchange mine, load for load, for the best I ever saw.

This method, as Mr. Bommer justly observes, has the advantage over all others by enabling the farmer to have his manure when and where he wants it. I shall make another heap in a few days, mostly of green weeds, grass roots, &c. &c. when, if you desire, I will give you the result.

To make manure by this method is not costly, but somewhat troublesome; but what good thing can be obtained without trouble or expense?

I have thus, sir, given you a candid statement of all I know at present about Bommer's patent manure,

And remain, very truly,
Yours,

GEO. WOODFIN.

June 13, 1843.

From our conversations with Mr. Woodfin, says the editor of the Planter, we know that this report is, as it should be, as careful and guarded as possible. He felt the responsibility of the task imposed on him, and determined to say nothing, however sanguine his anticipations might be, that could, by possibility, induce the public to think more of this invention than it deserved. For our own part, from what we have seen and heard of this experiment, we feel authorized to say that, which we never felt at liberty to say before, that we are fully satisfied of the great value of the invention. We do not doubt that a certain degree of particularity is required in following the directions that does not belong to some men, and which would deprive them of the benefit of the method, at least to the greatest perfection; so there are some persons, as every physician will tell you, who cannot be induced to administer three successive doses of medicine according to the simplest prescription. But in the hands of any farmer who will strictly follow the method as it is explained in Mr. Bommer's pamphlet, this invention, we believe, is worth ten times the price at which it is to be obtained.

Mr. Woodfin speaks of the method as being "somewhat troublesome." We wish he had been more explicit on that point: large quantities of water are used in the process, and Mr. Woodfin's heap was so situated as to make the application of this material laborious; but nine times out of ten, it may be so located, that any quantity of water may be conducted to it with little or no labor at all: we do not know, but think it likely that it was to this portion of the process, that Mr. Woodfin chiefly alluded in the expression quoted.

As to the time required exceeding that specified by Mr. Bommer, it must be remembered that this was the first experiment in a process entirely new, where the operator, without any experience, was compelled to rely wholly upon the printed directions contained in the pamphlet. Mr. Woodfin does not doubt, that, by avoiding an error committed in the first process, the result could be effected in the time required.

If the chemical properties of this compost are what Mr. Woodfin supposes them to be, of which he is much more capable of forming an opinion than we are, if it is indeed superior to stable manure, it is hard to estimate the value of the invention.

ROOT CULTURE

The flattering reception which my communications on the culture of Rutabagas and White Belgian Carrots, have met with in the Southern Planter, emboldens me to try my hand again. I have not the vanity to suppose that I can enlighten the readers of your paper, but if I can even be the means of directing to this subject the attention of some of the planters, who are skeptical of the value of root crops, in comparison with Indian corn, and induce them to make a fair trial, I feel convinced they will throw aside their prejudice and adopt their culture hereafter, to a certain extent. I would not wish to be understood as recommending the cultivation of roots in preference to corn, but an acre or two in roots will add much in the economy of feeding stock; enabling the planter to keep more and keep it in much better condition too; and the more stock, the more manure, and the more manure, the greater the crops.

Prejudice and conceit are the offspring of ignorance, and the great barrier to agricultural improvement. The first requisite to improvement, in any business, is the conviction, that we *can* learn; the next, that we *will* learn. And it perhaps is invariably true, that the more we *do* learn in useful knowledge, the more we become sensible of our comparative ignorance, and the more we are anxious to learn. This results not only from a wish to serve ourselves, and multiply our enjoyments, but from a sense of sacred duty to society.

I am aware that it is generally supposed, at the South, that the same labor and the same expense, will obtain more nutriment from an acre of corn, than from an acre of any root crop whatever. But such is not the case here at the North. From our soil that will yield forty bushels of corn to the acre, we can get from four to five hundred bushels of rutabagas, and from three hundred and fifty to four hundred of carrots, or mangold wurtzel, which, for milch cows and young stock, we consider of great value. They have not the fattening qualities, but are considered to exceed all kinds of grain in growing flesh. One advantage the root culture has over corn is, that it does not exhaust the soil so much, as it draws a great proportion of its food from the atmosphere; besides, rutabagas can be sown after the other seeds, and harvested after all the other crops are secured, and no growth leaves the soil in better order for a succeeding crop.

The introduction of the root culture into Britain forms one of the most important eras in the improvement of British husbandry; and its introduction into our country will ultimately prove highly beneficial. And that they can be grown south, and in Virginia too, is evident from the following, which was published in an early volume of the "Albany Cultivator." Mr. W. S. Morton, of Prince Edward, in a letter to the editor says, "That our soils are well adapted to the culture of the rutabaga I have demonstrated, to my own satisfaction, by a successful trial, on a moderate scale, for a number of years. I have cultivated mangold wurtzel last year on about the fourth of an acre, and succeeded to the astonishment of all who saw the crop."

If the root culture can be made to succeed in Virginia, of which I have but little doubt, I should not at all be surprised to hear that the lands there should double in value in the course of a very few years. In fact, I am so well convinces of it, that were I to sell the farm I now

occupy, I should turn my face to Virginia, and take a *look* at some of the now considered worn out lands before I settled down again.

And now, my good natured readers, permit me to recommend, in the culture of either variety of roots, the *ridge system*, which I have adopted, and given in the first number and fifth page of the current volume of this journal. In this plan the labor and tediousness in the first working is much abridged, and can be done by the younger or aged hands, and after a little practice, becomes less irksome, and not such a tedious job after all. Try it, and let us hear of your success through the columns of this paper.

C. N. BEMENT.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

MARL.

In presenting to the readers of the "Cultivator," the communication of "A BURKE PLANTER" on the subject of Marl, we take great pleasure in calling their attention to its contents.—Regarding as we do the subject of manuring as of the highest importance to the whole planting community of Georgia—particularly those sections long settled—we cannot better devote our space than to its elucidation. For upon the successful application of manure depends, in a great degree, the arresting of that continual tide of emigration westward, which is constantly and rapidly depriving us of our best and most enterprising citizens, and in an especial manner does the prosperity of the State and the success of the great agricultural interests depend upon the adoption of an enlightened system for the improvement of lands. Entertaining these views of the great importance of this subject to our planters, we welcome most cordially "A BURKE PLANTER" to our columns, and trust he will not cease his labors in so good a cause, but continue to enlighten us and our readers upon a subject with which he appears so familiar. We have indeed much need of such laborers in the field, and we sincerely hope he may not stop by the way side, but continue his efforts until he has induced others to join him in this great and important work of resuscitating the exhausted lands of Georgia.

TO STOP BLEEDING AT THE NOSE.—An acquaintance called a few days since to say, that one of his family having suffered from a profuse bleeding at the nose, after a fruitless resort to various remedies, some one laughingly suggested that the patient should hold up his left hand, a remedy that had been recommended some where in the newspapers: the suggestion was laughingly adopted, and the effect was no less surprising than satisfactory. Our informant only vouches for the fact that in this case the bleeding ceased after the hand had been held up for about three minutes. Whether the relation of cause and effect exists, or whether it will ever happen again he does not pretend to say.—*Southern Planter.*

COTTON BAGGING.

To the Planting Interest of South Carolina, on the manufacture of COTTON BAGGING *from inferior Cotton.*

During a recent journey to the southwest, I travelled with a gentleman, whose sagacity, information and practical experience, appear but as hand-maids to his usefulness and philanthropy.

The conversation turning on the condition of the Southern States, on the Atlantic, growing cotton; it was observed, that the desideratum at present of such importance, would be to manufacture with our inferior qualities of cotton, our own cotton bagging. The low price obtained for cotton, made this economy indispensable—also from our inability to compete, or keep pace with the richer soils of the southwest, where quantity compensated for price, from there being no chance in the scheme of compensations, in the administration of government, or acts of Congress, of receiving any equivalent—or any equivalent from the States that are now protected in the manufacture of bagging. Every view of the subject shewing the necessity of great economy, as far as South Carolina is concerned, and this branch of industry deserves immediate and strict attention.

My companion, who is an old and respectable merchant, and extensive ship-owner, has devoted some reflection to the subject I now bring before your country readers. As a cotton buyer, he says, he would prefer to purchase cotton packed in such domestic bagging, as can be easily manufactured in the State where cotton is produced, to that packed in hemp bagging, either foreign or American. This preference is given, because it is less liable to damage than hemp bagging, which from exposure is constantly apt to rot.

But this preference is given, provided care and skill are used to give the bagging made of cottod proper strength. This can be done, by attention in the first place, in making *a clean, pure warp or chain, free from defect and strong*—this part of the manufacture requiring most of the attention. The *thread* to be made about the same as that of the hemp bagging, and the square yard to weigh also about the same.

The additional advantage to which particular attention is invited, is, *to the filling or woof*, which requires less labor than that usually bestowed on it, *being only twisted sufficiently as not to be broken by the shuttle;* for this the most inferior cotton will answer, and the bagging thus made, will be found to resist the wear and tear to which it is always subjected, and most of all, from the iron hooks used by the laborers—the tenacity or elasticity from the manner recommended, being greater than that of the bagging in use.

This is the result of experiment. As a large ship owner for many years, the attention of my friend was turned, consistently with his interest, to examine and test the various specimens of sail cloth, so as to select the choicest kind of that necessary outlay for ships. In this examination, English, American, French, Russian and Dutch were tested; the last was found to resist time and friction and superior to the rest, and in looking to the cause of its superior usefulness, it was at once seen, that while the greatest care in the manufacture was given to the chain or warp, the filling or woof was *loosely* put in, precisely as is now recommended to those who are willing to manufacture bagging after this manner; and from this statement, it appears obvious that the same results will advantageously follow the mode above detailed.

The cost of machinery, it is said, cannot exceed $1500, to those who enter into it exclusively as a business; but to the planter who is in the habit of manufacturing his domestic cloth, the additional expense to what is so provided, will not be much.

It is out of place here to show, that our small and suffering State pays about four per cent on value of the cotton crop, to foreign countries and to Kentucky, for the greatest part of which she receives no equivalent whatever, in the shape even of barter; and for which she pays in gold and silver, or its equivalent. If from three to four hundred thousand dollars, so paid annually, can be saved by domestic industry, it becomes highly necessary to make the effort.

CAROLINA.

Southern Agriculturist.

CRITERION FOR JUDGING STOCK.

At the annual meeting of the State Agricultural Society of New York, held in January last, the writer called the attention of the Society to the propriety of erecting a standard of form, and every point necessary to constitute a perfect animal, to be noticed according to its influence, in the decision of the judges. This excited considerable interest, and elicited some debate as to the manner in which it could be accomplished, and finally resulted in the following resolution, offered by Mr. Rotch:—

"*Resolved*, That the Executive Committee be requested to call a meeting of breeders, at such time and place as they may deem proper, for the purpose of discussing the different points of merit in domestic animals, with a view of arriving at some definite opinion as to the points most desirable to be obtained in breeding."

As this subject is not only a very interesting, but a very important one, and requires some investigation, I am induced to throw out some hints and solicit the opinions and ideas of others on the subject, through the columns of this journal.

Suppose, for instance, to illustrate my ideas, the following should be agreed on as the points, as far as they go, for comparison, of horned cattle, and that animals possessing the greatest number of these points, shall be considered most meritorious:—

1. Head small, with a bright and prominent eye.
2. Hams small and tapering.
3. Neck small where it joins the head—large where it joins the shoulders.
4. Brisket broad, deep, and projecting well forward.
5. Shoulders full and no hollows behind them.
6. Body deep, round and capacious.
7. Legs short, full and muscular above the knee—small below.
8. Loins wide, and broad between the hips.
9. Flank well let down.
10. Tail set on even with the line of the back, small and tapering to bottom.
11. Though last not least, a soft supple skin covered with a soft silky coat of hair.

Central N. Y. Farmer.

PLASTER.—A young farmer desires to know how he shall use plaster. Our advice to him is, to use it freely on all his crops, our opinion being, that, at the rate of a bushel to the acre, it will do good to any crop, and the more where the land may have been previously limed. Let him mix it in the proportion of one bushel to twenty cartloads of manure, as he may be preparing his manure to be hauled out, or sow it, in that proportion, after his manure may be spread out, and previous to its being ploughed in: let him spread it on the surface of his ground after being ploughed, and then to be harrowed in: let him put it, mixed with ashes, in the proportion of one bushel of plaster to five of ashes, in his corn hills, or potato rows, graduating the quantity of the mixture to a gill for each corn hill or potato set: let him sow it in the first named proportion over his grain fields, his meadows, and his old fields, and he cannot go amiss. The range we have here marked out, is extensive, but not more so than it is calculated to do good in: and, in a word, we will say to our inquirer, that he will find it to his interest to sow

it any where, where he may have growing crops, as it will attract moisture and food from the air and from the earth, and like a good nurse, dispense it to the growing plants in such proportions, and at such times, as may be required by their wants.

But while the agricultor may be providing plaster, let him not forget that it always acts best where, as we have before premised, the land may have been previously limed.—*Am. Farm.*

To Clean Looking Glasses.—Take a newspaper or a part of one, according to the size of the glass. Fold it small, and dip it into a basin of clean cold water. When thoroughly wet, squeeze it out in your hand as you would a sponge, and then rub it hard all over the face of the glass, taking care that it is not so wet as to run down in streams. In fact, the paper must be only completely moistened or damped all through. After the glass has been well rubbed with the wet paper, let it rest a few minutes; and then go over it with a fresh dry newspaper (folded small in your hand) till it looks clear and bright—which it will almost immediately, and with no farther trouble.

This method (simple as it is) is the best and most expeditious for cleaning mirrors, and it will be found so on trial--giving a clearness and polish that can be produced by no other process. It is equally convenient, speedy, and effective. The inside of window panes may be cleaned in this manner, to look beautifully clear; the windows being first washed on the outside. Also the glasses of spectacles, &c. The glass globe of an astral lamp may be cleaned with newspaper in the above manner.

Dusting Furniture.—If a hand-brush is used for dusting furniture, it should always be followed by a dusting cloth. A brush merely disturbs the dust without taking it up or absorbing it; and is only useful in dislodging it from crevices. Therefore, if the dust is not afterwards wiped up in a cloth (which should be frequently shaken out of the window) it floats about the room, and settles again; being only removed from one place to spread itself on another. A yard of sixpenny calico will make two small dusters, or one large one. They should be hemmed, that the servants may not regard them as mere rags, to be torn up, or thrown away when dirty.

Miss Leslie's Magazine.

How to Mesmerise Lice on Plants.—A correspondent of the Macon Telegraph says:—"If you think the following is worth any thing, you can let your readers see it. I don't think there is any mistake in the matter. I tried it on two plants that were covered with lice, and out of the whole number I could not find one live one. I have found great difficulty in saving rutabaga seeds, and this year they were ruined before I could find a remedy. After trying a great many other things, I thought of the following, tried it, and found it effectual.

Take a little barrel that has but one head, and enclose the plant that contains the animals to be mesmerised under the barrel, then with a pipe, (or in any other way,) fill the barrel with tobacco smoke, then draw the dirt carefully round the mouth of the barrel, so as to prevent the escape of the smoke. Let the barrel continue there for twelve hours, (perhaps a less time would answer,) and it will be found that the animals are one and all completely mesmerized. No mistake about this matter. So if plants that have been left for seed are treated in this way, it will be found that their liceships are completely disqualified for doing mischief."

A correspondent of the Albany Cultivator says—"I have at various times tried several expedients to destroy caterpillars, and among other things turpentine, sulphur, &c., but have invariably failed, until I discovered that the spirits of hartshorn, applied by means of a sponge attached to the end of a pole, and thrust into the midst of the web, caused instantaneous death to all living matter it touched."

FEEDING HORSES.

Various opinions are entertained as to the best and most economical mode of feeding horses, and many experiments are on record that have been instituted to settle the question. The result seems to be, that at the ordinary prices of grain and hay, it is cheaper to keep horses on grain, than on hay, or on hay and grain. There is another important matter to be considered, however, and that is, is feeding entirely with grain, as conducive to the health of the animal, as a mixture of hay and grain. We do not believe it to be; and the general result of the experiments has been to show that it is not. Our own experience too would lead us to speak decidedly upon this point. We have tried feeding horses upon grain alone, and upon grain and hay, and found the latter the best for the animals. They were not so shrunk up or gaunt, there was more muscle and consequently more weight, and whatever may be thought of this latter quality in a race horse, where nothing but sinews and bones are required, every farmer knows that the road or farm horse is worth but little without weight. Feeding horses on grain alone, is like keeping a man on wheat bread solely; he will live for a time, but will finally sink under the experiment. In this case, the finer the flour the worse for the man. We have never had horses in better condition for labor, than when we have fed them with cut wheat staw, wet up in a tub with Indian corn meal.—It is evident there must be some proportion between the bulk and the nutritive power of food, and grain alone gives too much nutritive matter for the bulk. Oats, perhaps, approach nearer the standard than any other grain; but the use of these alone, will in a long run be found unadvisable.

One of the most carefully conducted experiments we have noticed, was the one made by Mr. Brotherton, near Liverpool; and he came to the conclusion that horses cannot be kept in a condition fit for work, if fed on grain alone. For nine years, Mr. Brotherton allowed eight horses three Winchester bushels of oats and one of beans, but no hay or chaff During this period he annually lost more or less horses, which he attributed to the quantity of grain being greater than the stomach could digest. This induced him to adopt feeding hay with his grain in the following proportion:—To eight horses he allowed one bushel of oats, one bushel of beans, and three bushels of cut hay, straw or clover; and he found them better able to do their work than before, and for several years after adopting the plan, lost but one horse from disease. Farmers, we are confident, have much to learn on the subject of feeding animals, and the health and good condition of the latter will, we doubt not, be found compatible with greater degrees of economy than has generally been practiced.—*Albany Cultivator.*

Wire Worms.—A friend has given us an account of an experiment made the past summer to prevent the depredations of the wire worms. A farmer had the previous year applied to a part of his corn, manure from the hog pen in which there was an abundance of cobs, and where this manure was used no injury was done by wire worms, while other parts were much injured by them where other manure was.

Supposing that the protection was owing to the cobs, he made an experiment the past season by putting two or three cobs into each hill, among the manure which was not from the hog-pen, on a part of the piece, and the rest of the piece was manured in the same manner, excepting the cobs-

Where the cobs were the corn succeeded well, and was not injured in the least by worms; while on that part where no cobs were used the wire worms did much damage. On taking up the cobs and examining them it was found that the pith was full of wire worms.

From the result of this experiment' it seems that the worms prefer the pith of the cob to the corn, and that nature has wisely provided for the protection of corn, when the ears fall to the ground, and the corn grows spontaneously, as the worms will find their favorite food in the pith of the cob, which allows the corn to escape their depredations.—*Farmer's Journal.*

Corns.—The common bean leaf, bruised and applied upon corns every night on going to bed for about a week, is, it is said, a certain remedy for these troublesome excrescences.

Whitewash that will not Rub off.—Mix half a pail of lime and water ready to put on the wall; then take a gill of wheat flour, mix up well in a very little cold water, then pour boiling water over it till it thickens. Pour it into the the white-wash while hot, and stir the whole together.

Destroying Insects.—The Gardener's Gazette recommends, as one means of destroying insects that are injurious to fruit trees and vineyards, to light piles of brush-wood when they are about depositing their eggs, attracted by the light, they will fly to it by myriads, and thus perish in the blaze.

AUGUSTA MARKET.

Tuesday P. M., July 5.

Cotton—The stock of cotton in our market and Hamburg was, on the 1st instant, 12,540 bales, and we presume that not more than one half the quantity is on planters' account. Our market for the past fortnight has been rather dull, not over 1000 bales, and at prices about ⅛ @ ½ cent less than our highest rate. We quote 4½ @ 6½ cents as extremes of the market—principal sales 5¼ @ 5¾ cents.

Money—Exchange on New York, Charleston and Savannah remains at par. Central Bank notes sell from 10 @ 12 ℔ cent discount. State 6 ℔ cent Bonds are in demand and will readily bring 65 cents.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, invariably in advance. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

Advertisements pertaining to agriculture will be inserted for one dollar for every square of twelve lines, or less, for the first insertion, and seventy-five cents per square for each continuance.

☞Post Masters are authorized to receive and forward money free of postage.

☞All communications must be post paid.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., JULY 19, 1843. No. 15.

COMMUNICATIONS.

GREENSBORO', July 10, 1843.

Messrs. EDITORS—The subscriber, living on the confines of the pleasant and healthy village of Greensboro', has there adjoining, and subdivided by the road leading to Park's Bridge, a large body of land, say some 14 or 1500 acres. These lands have been the best in the up country of Georgia, and land that has been good is more easily reclaimed, or made good, than that which has been originally poor. Now the owner of these lands just begins to find that it is the effort to cultivate too much land that is the ruin of Southern planters, and therefore, offers *for sale* the south half, say all on the south side of said road leading to Park's Bridge, containing about 700 acres, capable of being greatly improved, lies well, and the Georgia Rail Road running through it, which makes any land, however objectionable to some, more valuable.—These premises have all the necessary out buildings for a planter, except a good dwelling house, and there is a beautiful site for that. I propose to sell to some one that will be my competitor in the laudable enterprise of improving southern soil.

I think I can make off of my reserved half, more than I have done, in the old way, from the whole, and if I can get my man to set up side by side, me thinks we will provoke each other good works. Perhaps one way to do this is to learn to cultivate the soil, yes, southern soil, that which has been a good servant, but in the hands of hard task masters.

Now you and your readers will think this, the first from your new correspondent from Old Green, as a queer advertising sort of a production. Perhaps it is so, but the writer has been excited so to write, after reading a piece, and though laughable is yet not the less true, to be found in the Albany Cultivator, while conducted by the venerated Judge Buel, Vol. V. No. 10, called the "Looking Glass," and which I should be pleased to see copied for your readers.

And now, Messrs. Editors, in conclusion, I again say, send me my man; no Nick Bradshaw of a fellow, but the honest-hearted, industrious Horton, not afraid or ashamed to work, and work it right too, and I will give him, for a small consideration, a fair chance to have a home, yes, a "sweet home" as ever blessed any farmer, and we will vie with each other in the

"Delightful task,
To rear the tender stalk,
To teach the young plant how to shoot."

JNO. CUNNINGHAM.

The following is the article alluded to by Mr. Cunningham.

A LOOKING GLASS.

J. BUEL, Esq.—Dear Sir—When I was a boy, I can well remember how I used to be induced to wash my smutty face, by having a looking glass held before my eyes. For the same purpose, I have extracted the following picture of "a farmer," from the writings of that most eccentric and excellent writer, "Samuel Slick," in the hopes that if any of your readers should happen to see any part of himself therein, that he will improve by the view. Here it is.

"* * * That critter, when he built that wrack of a house, (they call 'em a half house here,) intended to add as much more to it some of these days, and accordingly put his chimbley outside, to sarve the new part as well as the old. He has been too "busy" ever since, you see, to remove the banking put there the first fall, to keep the frost out of the cellar, and consequently it has rotted the sills off, and the house has fell away from the chimbley, and he has had to prop it up with that great stick of timber, to keep it from coming down on its knees altogether. All the winders are boarded up, but one, and that might as well be, for little light can penetrate them old hats and red flannel petticoats. Look at the barn; its broken back roof has let the gable eends fall in, where they stand staring at each other, as if they would like to come closer together (and no doubt they soon will,) to consult what was best to be done to gain their *standing* in the world. Now look at the stock; there's your "improved short horns." Them dirty looking, half starved geese, and them draggle-tailed fowls that are so poor the foxes would be ashamed to steal them—that little lantern jawed, long leg'd, rabbit ear'd runt of a pig, that's so weak it cant curl its tail up—that old cow frame standing there with her eyes shut and looking for all the world as tho' she's contemplating her latter eend—(and with good reason too,) and that other reddish yellow, long wooled varmint, with his hocks higher than his belly, that looks as if he had come to her funeral, and which by way of distinction, his owner calls a horse—is all "the stock," I guess, that this *farmer* supports upon a hundred acres of as good natural soil as ever laid out door. Now there's a specimen of "Native Stock." I reckon he'll imigrate to a warmer climate soon, for you see while he was waiting to finish that thing you see the hen's roosting on, that he calls a sled, he's had to burn up all the fence round the house, but there's no danger of cattle breaking into his fields, and his old muley has larnt how to sneak round among the neighbors' fields o' nights, looking for an open gate or bars, to snatch a mouthful now and then. For if you was to mow that meadow with a razor and rake it with a fine tooth comb, you couldn't get enough to winter a grasshopper. 'Spose we drive up to the door and have a word of chat with Nick Bradshaw, and see if he is as promising as outside appearances indicate.

Observing us from the only light of glass remaining in the window, Nick *lifted the door* and laying it aside, emerged from his kitchen, parlor and smokehouse, to reconnoitre. He was a tall, well built, athletic man, of great personal strength and surprising activity, who looked like a careless good natured fellow, fond of talking, and from the appearance of the little old black pipe which stuck in one corner of his mouth, equally so of smoking; and as he appeared to fancy us to be candidates, no doubt he was already enjoying in prospective the comforts of a neighboring tap room. Jist look at him—happy critter—his hat crown has lost the top out, and the rim hangs like the bail of a bucket. His trowsers and jacket show clearly that he has had clothes of other colors in other days. The untan'd moccasin on one foot, which contrasts with the old shoe on the other, shows him a friend to domestic manufactures; and his beard is no bad match for the wooly horse yonder.—See the waggish independent sort of a look the critter has, with his hat on one side and hands in his breeches pockets, contemplating the beauties of his farm. You may talk about patience and fortitude, philosophy and christian resignation, and all that sort of thing till you are tired, but—ah, here he comes. Morning Mr. Bradshaw—how's all home to-day? Right comfortable, (mark that—comfort in such a place,) I give thanks—come, light and come in. I'm sorry can't feed your hoss—but the fact is, tan't bin no use to try to raise no crops, late years, for body don't git half paid for their labor, these hard times. I raised a nice bunch of potatoes last year, and as I couldn't get nothing worth while for 'em in the fall, I tho't I'de keep 'em till spring. But as frost set in, while I was down town 'lection time, the boys didn't fix up the old cellar door, and this infarnal cold winter froze 'em all. It's them what you smell now, and I've just been telling the old woman that we must turn too and carry them out of the cellar, 'fore long they'll make some of us sick like enough—for there's no telling what may happen to a body late years. And if the next legislator don't do something for us, the Lord knows but the whole country will starve, for it seems as tho' the land now a days won't raise nothing. It's actually *run out*. Why, I should think by the look of things round your neighbor Horton's, that his land produced pretty well. Why, yes—and it's a miricle too, how he gets it—for every body round here said, when he took up that tract, it was the poorest in the town. There are some folks that thinks he has dealings with the "black art," for't does seem as tho' the more he work'd his land, the better it got.

Now, here was a mystery—but an easy explanation of Mr. Slick soon solved the matter, at least to my mind. The fact is, says Mr. Slick, a great deal of this country is *run out*.—And if it warnt for the lime, marsh-mud, sea weed, salt sand, and what not, they've got here in such quantities, and a few Hortons to apply it, the whole country would *run out* and dwindle away to just such great, good natured, good-for-nothing, do nothing, fellows as this Nick Bradshaw, and his wooly horse, and woolless sheep, and cropless farm, and comfortless house, if indeed such a great wind rack of loose lumber, is worthy the name of a house.

Now, by way of contrast to all this, do you sse that neat little cottage looking house on yonder hummock, away to the right there, where you see those beautiful shade trees. The house is small, but it is a *whole* house. That's what I call about right—flanked on both sides by an orchard of best grafted fruit—a tidy flower garden in front, that the galls see to, and a most grand sarce garden jist over there, where it takes the

wash of the buildings, nicely sheltered by that bunch of shrubbery. Then see them everlasting big barns—and by gosh, there goes fourteen dairy cows—as sleek as moles. Them flowers, honeysuckles and rose bushes, shows what sort of a family lives there, just as plain as straws show which way the wind blows.

Them galls an't 'tarnally racing round to quiltin and husking frolics, their feet exposed in thin slips to the mud, and their honor to a thinner protection. No, no, take my word for it, when you see galls busy about such things to home, they are what our old minister used to call "right minded." Such things keep them busy, and when folks are busy about their own business, they've no time to get into mischief.—It keeps them healthy, too, and as cheerful as larks. I've a mind we'll 'light here, and view this citizen's improvements, and we shall be welcomed to a neat substantial breakfast, that would be worthy to be taken as a pattern by any farmer's wife in America.

We were met at the door by Mr. Horton who greeted my friend Slick with the warm salutation of an old acquaintance, and expressed the satisfaction of one habitually hospitable, for the honor of my visit. He was a plain, healthy, intelligent looking man, about fifty, dressed as a farmer should be, with the stamp of "HOME-SPUN" legible upon every garment, not forgetting a very handsome silk handkerchief, the work throughout of his oldest daughter. The room into which we were ushered, bore the same stamp of neatness and comfort that the outside appearance indicated. A substantial homemade carpet covered the floor, and a well filled book-case and writing desk, were in the right place, among the contents of which I observed several agricultural periodicals. I was particularly struck with the scrupulously neat and appropriate attire of the wife and two intelligent, interesting daughters, that were busily engaged in the morning operations of the dairy. After partaking of an excellent substantial breakfast, Mr. Horton invited us to walk over his farm, which, though small, was every part in such a fine state of cultivation, that he did not even express a fear of "starving, unless the legislature did something to keep the land from running out."

We bade adieu to this happy family, and proceeded on our journey fully impressed with the contrast between a good and bad farmer, and for my own part, perfectly satisfied with the manner that Mr. Slick had taken to impress it indelibly upon my own mind.

Mr. Slick seemed wrapped in contemplation of the scenes of the morning for a long time. At length he broke forth in one of his happy strains. "The bane of this country, 'Squire, and indeed of all America, is having TOO MUCH LAND—they *run over* more ground than they cultivate and crop the land year after year, without manure, till it is no wonder that "*it's run out.*" A very large portion of land in America has been "run out," by repeated grain crops and bad husbandry, until a great portion of this great country is in a fair way to be ruined.—The two Carolinas and Virginny are covered with places that are "run out," and are given up as ruined, and there are a plagey site too many such places all over New England, and a great many other States. We havn't the surplus of wheat that we used to have in the United States, and it'll never be so plenty while there are so many Nick Bradshaws in the country.

The fact is, 'Squire, edecation is ducedly neglected. True, we have a site of schools and colleges, but they an't the right kind. That same Nick Bradshaw has been clean through one on 'em, and 'twas there that he larnt that infarnal lazy habit of drinking and smoking, that has been the ruin of him ever since. I wouldn't give an old fashioned swing tail clock to have my son go to college where he couldn't work enough to arn his own living, and larn how to work it right tu.

It actilly frightens me when I think how the land is worked and skinned, till they take the gizard out on't, when it might be growing better every day. Thousands of acres every year are turned into barrens, while an everlasting stream of our folks are streaking it off "to the new country," where about half on 'em after wading about among the tadpoles, to catch cat fish enough to live on a year or two, actually shake themselves to death with that everlasting cuss of all new countrys, the fever and agur. It's a melancholy fact, 'Squire, tho' our people don't seem to be sensible of it, and you nor I may not live to see it, but if this awful robbin' of posterity goes on for another hundred years, as it has for the last, among the farmers, we'll be a nation of paupers. Talk about the legislature doing something, I'll tell you what I'd have them do. Paint a great parcel of guide boards, and nail 'em up over every legislature, church and school house door in America, with these words on 'em in great letters—"*The best land in America, by constant cropping, without manure, will run out.*" And I'd have 'em, also, provide means to larn every child how to read it, cause it's no use to try to larn the old ones—they're tu sot in their ways. They are on the constant stretch with the land they have, and all the time trying to git more, without improving any on't. Yes, yes, yes, *too much land* is the ruin of us all.

Although you will find a thousand more good things among the writings of "The Clockmaker," I hope you will not look for a *literal* copy of the foregoing. And if ever this meets the eye of the writer of the "Saying and Doings of Samuel Slick," I beg him to excuse me for the liberty I have taken with his own language.

I remain your Agricultural friend,

SOLON ROBINSON.

CHEAP SUGAR BOILER.

Take two pieces of plank six feet long, sixteen or eighteen inches wide, two inches thick, dress them neatly, especially on the side intended for the inner part; take two other pieces, two feet long, dress in same way, cut in one inch two inches from the end of your side pieces, then put it together with 12d nails, forming a box two by six feet. This will form a box without lid or bottom. Now get you a piece of sheet iron, just three-fourths of an inch larger every way than your box; fasten the sheet iron on with 4d nails, at the distance of eight or ten inches, on the open side of the box, forming a bottom. Then turn down the ¾ inch all round, closing it fast at the surface with a hammer, and with a small punch insert holes of a size to receive a No. 12 tack, at the distance of ½ inch apart, which will effectually secure the sheet iron to the wood, and which will complete the boiler. Now for putting it up for use. Take brick and form an arch six inches smaller than the bottom of the boiler, which will give three inches bearing on each side; at each end the bearing should be 4 to 6 inches, and the front end of the arch should be built up to the top of the boiler, to prevent the fire from burning the wood, and at the end where the chimney is to be, the brick should also be built up between the boiler and the flue of the chimney. Thus you will see that the wood part of your boiler is entirely out of the reach of fire and will have no effect upon it.

If copper is thought to be preferable for boiling sugar, it can be put on in the same way.—You need have no fears that such a boiler will not answer the purpose. I have one that I boiled a large crop of turneps in last fall, which never failed in the least.

I make this communication for the benefit of those who have patches of corn planted for the purpose of making sugar this fall. The cost is but trifling and is in the reach of every farmer. It is good for many uses—on wash and scouring days you will find it quite the thing, and is excellent for boiling cow and hog food, &c.

A. GREENE.

P. S. The better plan is to get your sheet iron or copper first, then form your box ½ inch smaller, sides and ends.

Green Co., June 29, 1843.

STANFORDSVILLE, PUTNAM CO., July 8, 1843.

DEAR SIRS—I propose in this communication to give your readers my mode of planting and cultivating corn; but before I do so, I beg leave to return you my acknowledgements, and beg that you will excuse me for asking of you what you had previously promised. In a day or two after sending my first communication, I was looking over the fifth number of your paper and found that you had promised enough to encourage any planter that felt inclined to write for your paper, to do so mithout the least embarassment, and in your thirteenth number, you have renewed that promise without reserve, which induces me to try my hand again, and if my poor efforts should prove of any advantage to your paper, or any one of your readers, then I shall have done what I desire.

I will now return to my subject and, in the first place, say that my land is very broken, and for the purpose of preventing the hill side from washing off, I have got them nearly all ditched, consequently have to plant the most of my corn in drills, and always plant the land in corn that was in cotton the year before. I have the rows laid off seven feet apart, parallel with the ditches; make a bed with five scooter furrows, (deeply ploughed,) the bed is then split in the middle with a scooter plough, the corn is then dropt two feet apart, one to three grains in a place, and carefully covered with a hoe, (I never had a field of corn covered with the plough.) So soon as I get one field planted, the middle of the rows is broken up deep with scooter ploughs before we move to another field. By the time we have gotten through planting corn in this way, our attention is turned to that of preparing cotton land. By the time that is done and the cotton all planted, the corn, in good seasons, is all up and from 3 to 6 inches high. The ploughs are then put in the corn. I have colters put in good order to side the corn, run deep and close. The row is then ploughed deep with scooter hoes. The land should be properly and deeply broke by this plowing. I have my hoe hands to follow this plowing, thinning the corn out to one stalk in a place, and chopping out all the grass that may be in the drill, at the same time throwing some dirt around the corn. From fifteen to 20 days after this is done, the corn is from half leg to knee high. The shovel plows are then put in. A careful plower, with a good shovel plow, will run his furrows so as to make the dirt lap on the drill, which is about equal to a hoeing. This is the time for planting peas.—I have the rows plowed out, being careful to have the last furrow well thrown out; a hand

then follows and drops peas in said furrow; a plow then turns back and with one furrow covers the peas. If the ground is too dry for peas to come up, I have the rows left without the middle furrow being plowed out till rain, then one plow will run the last furrow in those rows as fast as a hand can drop the peas, and another plow will keep up with the covering. In fifteen or twenty days after the corn should have the last plowing, which is called laying by. This plowing may be done either with a shovel or sweep. My land being so broken, I generally give the last plowing with the shovel. After this much is done, when it is convenient, the hoe hands go over and chop round the peas and corn, cutting all weeds and large grass, if any.

I am well aware that this mode differs but very little from the general custom of cultivating corn. The difference is most in that of siding with colters, and many corn makers may side their corn with colters for aught I know, but I can say to those who never have tried siding young corn with colters, that if they will have colters made of a proper shape and try them, I am sure they will never repent it, especially those that have stiff land to cultivate.

It may seem to some at first thought, that seven feet wide for corn rows is giving too much distance; but a slight calculation will prove to them that 7 by 2 feet will give a good many more stalks on an acre than will be by 4 feet each way. By having corn rows less than seven feet wide does not do well for a pea row in the middle.

I am careful never to have my plows at work in my corn, or in any part of my crop, when the land is the least mirery. It is an injury to the crop as well as to the land to plow while it is too wet, especially land that has little or no sand in it.

It is well known to planters, that corn planted in the summer is of a more rapid growth than that planted early in the Spring. Perhaps there are but few that have taken any account how long it will take corn to come to rosting ears, planted at any season of the year. I have taken some account of this matter and am willing to give it to the public. Year before last I planted a lot that cows had been penned on, the 15th day of July, with the common gourd seed corn dry from the crib, and had roasting ears the 53d day after putting the seed in the ground. Last year I planted the same lot with the same kind of corn, and did not have roasting ears till the 64th day after planting—(last year it was planted the 4th day of July.) You will see there was a difference of 11 days. The difference was owing to the season—year before last it rained perhaps half the days in August, and the lot being on a hill side and very stony, could bear a shower every day or two. The ears were heavier and better matured last year than they were year before last. In both years, as the ears were pulled off for eating, (all hands had free access, both black and white,) the stalks were cut off at the ground and fed to the horses and hogs—every part was consumed by them to profit no doubt. The same lot was sown in barley each fall for the benefit of my poor calves, sheep, &c. I have planted the same lot in corn again this year, the 24th of June, and expect to continue it in producing two crops a year. I leave you to judge of its profitableness.

I beg leave to enquire, through your paper, if there are any of your subscribers who have the Kentucky Blue Grass in cultivation; if so, they will do me a favor by giving some account of it. I wish to get some of its seed, and would be glad to know how it thrives in this climate.

I also wish to know if any planter in this State has a corn and cob crusher; if there is one, I should be glad to know if such a mill is durable, and if they will crush the cobs small enough to be ground to meal in a grist mill? I have no doubt of the great saving planters could make by having such a mill, if they can be made to be durable and crush cobs small enough to be made with grain to meal in a grist mill. Horses or cows will eat every particle of corn cobs if soaked in salted water till they become soft. I have seen statements made, going to prove that there is one third as much nutriment contained in the cob as there is in the grain of corn that covers the cob. Whether this be a fact or not, I am not able to decide, but I have no doubt but there is considerable nutriment in cobs.

I am, sirs, yours respectfully,

JOHN FARRAR.

HOUSTON COUNTY, GA., June 29, 1843.

Importance of Hogs.—How the People of Georgia are imposed on by Spurious Breed, &c. &c.

To the Editors of the Southern Cultivator:

It is no longer a question in Georgia, should the cotton planter of the South raise his *bacon?* By long and sad experience the Georgia cotton planter has found it to be to his advantage to raise his own bacon: nay more, it is with him now a matter of the first magnitude, for without the article he cannot raise cotton. Bacon, from long experience, is known to be the most healthy *meat* diet in the world, particularly for negroes, who do most of the labor on cotton plantations; and as long as the negro children are fed bountifully upon bacon and bacon grease, &c., they are not attacked with worms; and it is a fact well known to physicians, that near one third of the deaths of negro children, from two to seven years old, are from worms. Good old fat bacon is (not a remedy, but) a preventive of that formidable disease. Being raised in the South, near the Atlantic, amid large and extensive plantations of negroes, my experience (not much circumscribed,) can testify to the truth of the above remark. In that region of country I observed, early in life, that the fatality of the negro children, caused by worms, was in equal ratio with the amount of bacon diet furnished them. The above remark is founded in truth, and will be made more evident by experience in future, and I consider the subject of great moment in subserving the ends of religion and humanity.

In order for the cotton planter to produce this article, so indispensible to his welfare, it is plain that the first step after making an abundance of all kinds of grain, is to procure the best breed or stock.

The very laudable and praiseworthy spirit manifested (only a year or two past) among our planters, to procure and raise a genuine stock, has exposed them to unpardonable impositions, equally as disgraceful as that one of *wooden nutmeg* memory.

Since this noble spirit has manifested itself among the planters of Georgia, from whence have they obtained their *blooded hogs?* Answer, from the Western States principally, and they have in like manner obtained their breed from the Northern States, and these have, in like manner, been supplied from the fountain head, Old England. Now soon as any one of us obtains one of these genuine animals, the next thing done is to *cross* the breed with our *scrubs*, and the same thing is done in all parts of the country. This spurious and mixed breed, pampered from the start, is, by our more enterprising bretheren of the West, hurried across the Cumberland Mountain, down into the beautiful and fertile plains of Georgia, with the name and character of the genuine stock. The credulous and unsuspecting Georgian, (with the milk of human kindness overflowing,) becomes the dupe of his more keen and sagacious neighbor of the west, and instead of getting the genuine blood he has only the half, and perhaps the quarter breed. For the stock, nine times in ten, was first mixed in the Northern States, secondly in the Western States, and hence we see a spurious and wretched breed of hogs, after much expense, swarming about almost every plantation in Georgia, to the great disappointment and injury of all. A continuation of such disappointments will humble that zeal and emulation which has just taken such favorable hold among our planters, and in disgust they will return again to their old station. Whoever will take the trouble to read the "Sketches of Travel," by Captain Barkley, an English agriculturist, through several of the United States, will become more acquainted with the humbuggery practised on us in the *articles* Grazier and Berkshire hogs, Saxon and Merino sheep, Durham cows, &c. The want of direct importation has made the Southern States "hewers of wood and carriers of water" for a long series of years.—Why have the people of Georgia been dependent on States 600 miles distant, for hogs of a spurious breed? Where is our much neglected but much beloved Savannah? as fine a sea port as any on the borders of the Atlantic, within the boundry of our State, to which we can, if we wished, have the genuine stock of every kind imported direct from any part of the English Islands, in from thirty to forty days. Why not avail ourselves of these signal advantages, which the Western States do not and cannot enjoy? But rather than import the genuine breed ourselves, we have preferred, heretofore, to pay extravagant prices for the *half* and *quarter breeds*, and hence we hear the remark almost in every company we approach, that "it is all a multicaulus speculation." But I am glad to know there is yet intelligence enough left among some of us to estimate these matters properly.

When will the unsuspecting planters of Georgia arouse from their slumbers, so opposed to the interests of us all?

I have no doubt that if we had the genuine breeds, we could raise hogs, sheep, cattle and horses in Georgia to as great perfection as in any part of the world, and it will certainly not be contended by any, that it is not to our advantage to do so, at least for our own supply.—From some little experience I am confident we can raise double the quantity of pork with the same amount of grain, from the genuine breed, than we can with our old common stock. With good common crab grass pastures, (which every planter in Georgia can have,) it is surprising to see how little grain will make the hogs grow and thrive. This remark is not intended to be applied to the spurious breed.

Georgia is one among the finest countries on the globe, the soil is naturally rich in most parts, and in order to see her favorable position relative to climate, all that is required is to cast the eye on one of her maps. Her mountains almost groan with the weight of the precious metals contained in their bowels. The gold richer than the "gold of Ophar" is here, and here we can have "cattle upon a thousand hills."

A Lover of Good Ham.

Athens, July 11, 1843.

Dear Jones—Our farmers have generally made wheat of better quality this year, than they have done for several years past. The fact which I wish made known is, that the crops produced from seed which had been soaked in a solution of blue stone, or in a strong brine, *and* rolled in lime, had *no* smut, whilst some crops, from seed with which no such precaution had been used, were rendered worthless by smut.

I raised in my garden last year, about half a peck, of a very fine white, flint wheat. This I put into a saturated solution of salt in water, the night before sowing. The next morning, in my absence from home, my old man began to sow it (in drills)—on my return I immediately arrested him, and made him roll the remainder in dry, air-slacked lime. Of that from seed *without* the lime nearly a fourth of the heads were *smut*, of the remainder, *not a head*. I sowed it on rather thin soil, in drills about 20 or 24 inches apart, made with the point of a garden hoe, covered it lightly, and spread on the surface a very little fresh stable manure, and covered the manure with powdered charcoal. The exceeding cold weather of the winter did not seem to affect it at all. It came in a fortnight earlier than the *red May*, (the common crop of the country,) and yielded me, notwithstanding the loss of the smutted heads, nearly five bushels.—The ground less than one quarter of an acre.

Whilst making you a *communication*, it may not be amiss to say, that I procured Bommer's method of making vegetable manure, and made an experiment on *tan bark*, before I saw, in the Albany Cultivator, Mr. B.'s opinion of the project. I have not yet tested the fertilizing properties of the compost, but from the trial of the *method* I have made, I entertain no doubt of its entire success in converting *straw*, cornstalks, shucks, &c. into perfect compost, and in the time prescribed. But one fact the farmer should know, and that is, that it can only be made at a *branch* or *creek*. And before the method is bought, the farmer must consider whether his farm or field is so situated with respect to a stream of water, that he can *profitably* transport his stalks, straw, &c. to the stream, and afterward convey the manure to his field, in all which distance and the declination of the hill are important matters.

In an extract in your last paper on this subject, is the remark, that this vegetable manure "may be made *any where*." This may be *literally* true, but the trouble of *hauling* the water to the heap, is tenfold the labor of hauling the material to the water; for it requires something like 1500 or 1800 gallons of water to apply to 1000 lbs. of straw. H.

My *Berkshire sow* does not *breed*—what is to be done in such a case? She is in possession of all the appetences and advantages in such cases made and provided.

COTTON BAGS.

Georgia Cottons, although desirable in foreign markets for quality, are derided for the bungling and awkward manner in which they are packed up. The round bales of Georgia are scouted at by buyers, whenever cotton of equal quality can be got in square bales. The planters of Georgia are far, very far behind their neighbors, if not in the culture of our staple, at least in their manner of preparing it for market. There is no excuse for them in persisting in this barbarous mode of packing cotton, and making themselves not only subject to reproach and ridicule, but very materially effecting their pecuniary interest. In sea ports, whether at home or abroad, a Georgia planter is considered as a slovenly farmer, one who is behind the age, and who can neither profit from experience or observation; and for no other reason, but because his cotton, which is equally clean and as well ginned as the cotton from other States, comes to market—in the uncouth, cumbersome and unhandy form of *round bales*.

We have taken some pains to collate a few facts, which we trust will not be wasted on our country friends.

The receipts of cotton the past season in Macon, will be from ninety-three to ninety-five thousand bales, of which quantity fully 75 per cent are packed in round bales. The difference in freight between round and square bales from Macon to Savannah by the rail road is in favor of square bales 25 cents. From Savannah to any port in Europe ¼d per lb.—$1. And a preference is always given by purchasers to square bales of at least ⅛ cent per lb. for the reason that cottons thus packed always go to market in better order. The Georgia planter is a sufferer in another way, in consequence of the bulk of cotton coming from the up country into Savannah in round packages. There is less competition in that than other Southern markets, for the reason that round bales do not suit the continental markets in Europe, consequently the many ships which are loaded for the continent, go to Charleston, Mobile and New Orleans for their cargoes, that would come to Savannah, if the crops were packed in square bales. At present there are but two markets for Georgia cotton—our domestic manufactor and Liverpool—the former being so small a competition, we are left almost entirely to the mercy of the Liverpool merchant.

We hope to see this evil, if not removed, at least very materially corrected the ensuing season. It strikes us that the Savannah merchant can apply a more effectual remedy to this mischief. Let him make the difference in prices for cotton packed in square and round bales, greater than it even now is, and the stubbornness and prejudices of our planters for antiquated and old fashioned notions, will have to yield to considerations of interest.—*Macon Mess.*

MULES.

The following, cut from a Prince George's paper, on the comparative value and economy of the horse and the mule, has been kindly forwarded to us, for the Cabinet, by the writer, J. S. Skinner:

Review of the premiums offered by the Agricultural Society of Prince George's County, Md.—For the best Jack $5; *for the best Jenny* $5; *for the best pair of Mules* $5.

The prejudice against the mule seems to be as inveterate as that which impels the heel of every son of Adam to "bruise the serpent's head," whether it be the head of the innocent water or the harmless black snake, or the viper or copper head, bloated with poison.

Instead of this invidious distinction by the committee in favor of the horse, offered the highest premiums for that very expensive animal, in all his ages, forms and sexes, young and old, quick and slow, male and female, it were better, we should think, to have held up the highest premium to him whose *mule power* should bear the greatest, and *horse power* the least, proportion, the one to the other, in use on his plantation! As for rewarding the mere exhibition of the "best pair of mules," what length of merit can be discerned in that, unless it be that it implies length of purse to give the highest price? If driven to the ground in the owner's own carriage, in lieu of a pair of $500 Vermont horses, that would be quite a different matter. The mode of taking the last census was very defective in many respects. For example, it only gives us the number of horses and mules in the aggregate; while here, at once, is an agricultural problem, which requires for its investigation that we should have accurately and separately stated the number of each.

Twenty years ago it was estimated that the horses in England consumed the product of twenty millions of highly cultivated acres; and Sir John Sinclair calculated the keep of one horse to be equal to the product of five acres. Let us suppose constant work to be provided, as it should be, for every horse that is kept on a plantation; does not true economy, as well as humanity and justice, demand that each horse so worked should be well fed? And if so, may not each horse be estimated to consume, at two and a half gallons a day, $56 of corn. Add to this $14 for other provender, and shoeing, and physicking, and you have an outlay of not less than $70 a year for every work horse, to say nothing of idle brood mares, colts, carriage horses, and other *non-producers;* a sum for each horse equal to the purchase of a first-rate mule, while the average life of the former will not more than half equal that of the latter.

Among planters in the South, whose position and circumstances are so identical with those of Maryland, the economy and advantage of the mule over the horse are universally admitted. The report of an Agricultural Society of South Carolina, in relation to this subject, may here be quoted where it asserts: "The mule is more easily raised than the horse, more able to bear heavy burdens, equally strong for the draught, more patient, equally docile, will live twice or thrice as long, capable of enduring much more labor, will do as much work in the same time, and will not be more than one-half the expense, as they will not eat more than one-half the grain, will make use of long forage, which the delicacy of the horse will reject, and will bear the heat full as well, perhaps better."

Should not these considerations induce planters to ponder and reflect how far it is expedient to aggravate, by their highest honors and rewards, that natural and costly predilection of our countrymen for horses, which may be said already to amount to a passion—one which had its origin in deeds and days long past of

Christian service and true chivalry;

but no more congenial with this utilitarian, money saving age of ours, than would be the vagaries of the Knight of La Mancha himself?

The last census gives for Prince George's county, Md., 4618 horses and mules. This we believe to be much short of the real number.—The aggregate of both for the State is returned at 92,220.

It is not extravagant to assume that 60,000 horses in Maryland might be well superseded by mules; and taking only ten dollars as the clear saving of each, here would be a reduction of annual expenditure—in other words, an increase of income amounting to $600,000, equal to the interest on the State debt.

In all steady continued draught, as in threshing, grinding, and other machinery, now so much in vogue, the excellence of the mule is most remarkable, and especially in his less liability to gall—an evil to which the horse is peculiarly subject, where his locomotion in harness is *circular*. On their value in service that consists of constant, steady hauling, an extract may here be made from some editorial remarks in an old volume of the American Farmer, then conducted by Mr. Skinner, now of Washington. Speaking of the decided preference given by the late Gen. Ridgely, of Hampton, to mules in the heavy hauling connected with his iron works, it is observed: "For some time the General indulged an old servant in keeping a single team of horses, but it was found that the mule teams performed their day's journey, hauling equal weight, sooner than the horses, by one hour; and the great value of the mules has been so well established, in the course of his ample experience, that they have superseded horses, with entire conviction of the great saving accomplished by the change. This information first derived from his manager, Mr. Green, was fully confirmed by the General himself."

Why, then, let it be repeated, in reference to these two animals, make fish of one and flesh of the other? Offering $76 in premiums for the horse, and $15 only for "jack, jenny and mules;" and that, too, under the authority and sanction of gentlemen who cannot be too much admired for their public spirit and honorable intentions; nor too closely imitated in their individual practice and general management.

As to the more general use of the mule in light harness for the road, the common impression is, that he can't be made to *travel fast enough*. Nobody likes rapid motion more than the writer of these crude, but well meant and respectful strictures; and he would take leave to inquire, who has given to this neglected hybrid a patient and fair trial, to see how much his speed may be improved? Let it be considered how long it takes to bring a crack trotter, such as Ripton or Confidence, to his best! Hiram Woodruff or Bill Wheeler, the American Chifneys among trotting jockeys, never think of taking a horse in hand, to train him for this pace, until after he reaches his sixth or seventh year; and they can hardly be said to get to their best work until they fall into their teens. Old Top Gallant performed his chef d'œuvres after he was twenty! When the mule has been in like manner taken up, and systematically trained for the trot, and it is found that he cannot be driven at the rate of eight miles an hour, it will be time enough to pronounce him impracticable in that pace; but the writer knows him to be master of that rate, for he has ridden with two others beside Gen. James Shelby, who drives nothing else in his private carriage, from Lexington out to his magnificent blue grass farm, eight miles, behind two mules of about 15 hands, within the hour, and without a touch of the whip; and learned from the General that he had driven a pair to the Blue-lick, a distance of forty miles, in six hours, stopping one hour on the way.

In lieu, then, of some of the premiums bestowed on breeding stock to give animals of slow draught, and on sucking colts, would it not be more politic to lend the countenance of the society to the rearing and more general adoption, for the roads as well as for the field, of a more economical and enduring power? Might not a premium be well offered, in the shape of a set of knitting needles in a silver case, or a butter cooler of ground glass, with a cow reposing on its silver lid, to the wife of the planter who shall accompany him to the cattle show, in a plain light carriage drawn by a pair of best broke mules? To the wife, because it is doubtful whether, without her consent, this great desideratum in rural economy ever can, or, perhaps we should add, ever ought to be achieved! Were it to be imagined that the fact would have any weight with our republican housewives, it might be added, that the medals struck in honor of Agrippina, a heroine whose life was adorned with the most noble virtues, bear on them the image of a mule; and a gentleman at my elbow reminds me that he has seen Charles the X setting out for his royal palace at Fontainbleau, 13 leagues from Paris, driving six splendid black Spanish mules of Andalusian blood!—But it would be a libel, of which I should never be guilty, to suppose that an American matron could be influenced by any motive so strong as her ambition to promote the independence of her husband, and to set to her friends and neighbors an example of economy and good sense.

Farmers' Cabinet.

BUTTER MAKING.

Messrs. Gaylord & Tucker—I observe in your last paper, that some lady is desirous of obtaining particular information in regard to the process of making and management of butter. For fear that those *actively* engaged in the employment may not take time to satisfy her inquiries, I have concluded to give her and her "neighbors" my own ideas on the subject, derived from past experience.

Some thirteen or fourteen years ago, with but little more knowledge of the matter than your correspondent professes to have, I undertook the charge of a small dairy. I found there was an English dairy woman in the neighborhood, whose butter was the criterion by which all other butter was judged, when submitted to the epicures in that article. With the aid of her friendly instructions, and such books on the subject as I could resort to, a satisfactory result was obtained.

The first requisite to the production of good butter is *good cows*. By good cows, I mean those that will give plenty of such milk as will yield a large quantity of good butter. It is a well known fact that cows running in the same pasture, or fed precisely alike, will afford butter varying much in quality. A poor cow is more injury to the dairy than she is worth, and should therefore be rejected. I have always observed that cows which gave the richest milk, generally have soft, velvet-like *yellow* skins. I will not say of what tint the *hair* should be, as I should not like to commit myself on the long vexed and important question of *color*.

Cows, to yield good butter, as every farmer and dairy woman knows, should have *good keeping*. Plenty of good succulent food, both in summer and winter.

The *Dairy House* should be cool and airy, commanding plenty of pure cold water, either by a running stream, or by pipes laid from a well; ice, too, is an excellent auxiliary. Wood or stone troughs, which can be kept full of water, are very good to set the pans of milk in.

Great care should be taken that every thing connected with the dairy should be managed with the most scrupulous *neatness*.

If milking is done but twice a day, the time should be divided as nearly equal as convenient. The milk should be carried to the place where the dairy work is done, immediately strained, and left a short time for the warm steam to pass off before it is carried into the dairy.

Of all the pans I have used, I much prefer the tin. They are lighter, less expensive in the end, and easier kept clean. Zinc is not fit to keep milk in at all, as a slight degree of acidity decomposes a certain portion of the zinc. From 24 to 48 hours is sufficient time for the milk to stand before skimming. I should much prefer that milk should never *sour* before the cream is taken off. Some persons think it highly important that cream should acquire a certain degree of acidity before churning, but I confidently affirm that the best butter I ever made, was from cream that was perfectly sweet when the churning was commenced. The remarks of a writer in a late number of the "Maine Farmer," so exactly coincide with my own views, that I will give them in his own language:

"Butter is an article which is very ready to receive a flavor from any gas, or from contact with other substances, unless it is entirely freed from every particle of its mucilage." He says further, that "the mottled or streaked appearance in butter, is owing to the coagulated lymp, coagulated from souring; it is indissoluble in water, and can never be worked out of the butter. Salt should not be added at the *commencement* of the first working, as it is known to every housewife that salt will curdle sour buttermilk, and should also be known that curd once formed in with butter, can never be worked out. They can work out the whey and leave the butter apparently dry, but the cause of the mischief is still left. Incipient decay has already commenced in the coagulum or curd, and will proceed, unless something can be applied that will put an entire stop to it."

The frequency of churning may be regulated according to the quantity of cream and state of the weather.* The best churn for a moderate sized dairy, that I have any knowledge of, is "Gault's Patent." It operates easily and effectually. It may be had of Ruggles, Nourse & Mason, Boston, and probably at other implement stores. In the largest size, from one to twenty five pounds of butter can be made at a time.

Experience has led me to deprecate the practice of *washing* butter when it can possibly be managed without. Butter that comes so soft as to require cold water to harden it, cannot by washing be made to keep sweet any length of time. When the butter is taken from the churn, and the buttermilk worked out, put in 1¼ oz. best salt to one pound of fresh butter; or if the buttermilk is not well worked out, more salt will be needed. Set it away in mass for 24 hours in a cool place, when every particle of moisture should be extracted, and the butter made into rolls or prints for use For this purpose a flat smooth board or marble slab is necessary; a flat surface preferable to a dish, as you can so much more easily get rid of the moisture from the butter. Some use a wooden slice or spatula to handle the butter with; this requires more strength, especially if the butter is hard, than is required by the use of the hand alone. To prepare the hands for working butter, rub them well with wet corn meal, then wash in water as hot as can be borne, plunge them in cold water for a moment, and you are ready to handle butter in the warmest weather without melting it, if it is done early in the morning, before the hands get heated by exercise.

Butter for keeping should be made when the weather is cool. To every pound of fresh butter, add 1¼ oz. best salt and ¼ oz. saltpetre, taking particular care to extract every particle of moisture, as on this mainly depends the future excellence of the article. Pack close in stone jars. Doubtless every one has observed when butter is not well worked, the watery particles diffused through it, destroying that waxy appearance so much prized by lovers of good butter.

Salt should never be used for butter without sifting; it is extremely disagreeable to encounter lumps of salt, either in spreading or eating, what should be such a luxury.

Winter butter can be made as good in color and consistence, as at any other season of the year. This assertion will perhaps appear strange

*In cold weather the cream should be brought to the fire some time before churning. I think about 65° Farenheit is about the right temperature.

to some of *my neighbors*, as the bad quality of the butter in our market has been a subject of continual complaint and inquiry during the past winter. To find one of the causes, no one need go far. Let him only ride 20 miles in any direction, during the severe winter just past, and he would have seen hundreds of these poor abused creatures, the cows, standing around, (not even permitted to enter,) the log barns which appear to have been made expressly for *free ventilation*, chewing the cud, not of "sweet and bitter fancy," but some old dry cornstalk, or perchance, if so fortunate as to have a saw mill in their vicinity, a nice strip of bark gnawed from a log that had lain in water till sour and half rotten, looking for all the world as if they could give their owner more tears than milk. This is no "fancy sketch"—and now need one ask why the butter is poor?

With good cows, well fed, and a place to raise the cream without freezing, there is no difficulty in the matter. If the natural richness of the milk does not impart sufficient color, take deep colored carrots, (the Altringham is best,) grate fine, pour boiling water on the pulp, and strain into the cream till sufficiently colored; so far from imparting a carroty taste, it gives additional sweetness and richness to the butter. Yolks of eggs beaten up, two to a gallon of cream, do very well. These are the only coloring materials I ever used.

I have extended this communication to a greater length than I intended, and if I have been led into prolixity, (which, by the way, I detest,) a desire to assist beginners, for whom I have written, must be my apology. Should any experienced dairy woman be in possession of important facts on this or any other subject, which are not familiar to all, I hope she will not withhold them from your readers. M. W. H.

Albany Cultivator.

EXPERIMENTS WITH SALT.

GENTLEMEN.—I with pleasure comply with your request, and give you the detail of my experiments in the use of salt as a manure. In the spring of 1838, we broke up six acres of sward land that had been mowed a number of years, intending to plant it to corn, but observed when ploughed that the ground was infested with worms– the yellow cut or wire worm, and black grubs. As we had mostly lost our corn crop the year previous by having the first planting almost entirely destroyed by the corn-worm above described, we expected a like calamity would follow the present year, unless some preventive could be used to destroy the worms; and, having frequently and unsuccessfully used all the recommended remedies to destroy the corn-worms, we were induced, at the suggestion of an English laborer, to try salt. After the ground was thoroughly harrowed, five bushels per acre was sown broadcast, leaving a strip of near half an acre on each side of the field, to satisfactorily test the experiment. The whole was then planted to corn and potatoes. The corn on the part no salt was sown was mostly eaten up by the worms, and was reploughed and planted to potatoes. The potatoes on the whole lot were a good crop, but decidedly better where the salt was applied. I regret that we did not ascertain by measurement the actual result. There was a very perceptible difference in the appearance of the vines during the whole summer. On the part where the salt was sown they grew larger and were of a darker green color, and continued green longer in the fall than the others. In the spring of 1839 we spread on a good coat of manure, and planted it all to corn, except about half an acre of the salted land, which was planted to Rohan potatoes. The Rohans were the best crop of potatoes I ever saw. Seed planted (two and a half bushels) produced over three hundred bushels. The largest potatoe weighed four and three fourth pounds. The corn was a heavy crop, but was not measured. The summer was very dry and hot; but the corn on the salted land did not appear to suffer at all from the drought, while the other was considerably injured. The salted land appeared always moist, and the growth of everything upon it was very rapid. We found great difficulty in keeping the weeds down. After three successive hoeings, we were obliged in August to give it a hand weeding. Spring of 1840, intended to have stocked the land down for meadow; but, thinking it too rich for oats, planted potatoes without manure. Crop good. The effects of the salt still very apparent. Adjudged to be one-third more potatoes where the land was salted.

Spring of 1841, sowed a part of the lot to oats—the remainder to potatoes and onions without manure. The onions were a great crop. The summer was very dry, but they did not suffer; while other crops in this neighborhood, on similar soils, were nearly destroyed by the drought. The oats were a heavy crop, and much lodged on the salted part. The clover grew well and produced a fine crop of fall seed. This I cannot account for, except by supposing that the salt kept the land moist, or attracted moisture from the atmosphere, as I know of no other piece of land in the town that was well seeded last year. It was almost an entire failure; and the most of the land stocked down last spring has been or will be ploughed up in the spring to be re-seeded.

We sowed salt the same spring on a part of our meadows. The grass was evidently improved, the result satisfactory, and we shall continue to use it on our meadows. I shall not at this time force upon your readers any opinions of mine respecting the manner in which salt operates beneficially upon vegetation or the soil. The following quotations from English authors, if you see fit to publish them, will show that the subject is not a new one; and perhaps your readers may glean some information from them.

In Europe much has been said and written to prove and to disprove the utility of salt as a manure. Without entering at all into their ideas of the *modus operandi*, we may judge from the effects of experiments. I may say, however, that it has been supposed beneficial in small quantities, by its tendency to promote putrefaction, and injurious in large proportions, because it then exerts its antiseptic powers. It has been supposed of benefit, by destroying snails, grubs, moles, &c. in the ground.

"It is observed by Dr. Darwin, that as it is a stimulus which possesses no nourishment, but may excite the vegetable absorbent vessels into greater action than usual, it may, in a certain quantity, increase their growth, by taking up more nourishment in a given time, and performing their circulation and secretions with greater energy. In a greater quantity, its stimulus may be so great as to act as an immediate poison on vegetables, and destroy the motions of the vessels by exhausting their irritability. The reports of experimenters on the use of salt as a manure have been as different as the soils on which their trials were made; owing, in some measure, to causes which can never be foreseen or controlled, and on which agricultural experiment so generally depends. In sandy soil, salt has been found to exert effects superior to eight out of ten of the best manures. A quantity of ground was prepared and divided into beds of forty yards in length by one in breadth. The beds were then sowed and manured by the following substances in the quantities mentioned:

"No. 1. No manure.
2. Salt, half a peck.
3. Lime, 1 bushel.
4. Soot, 1 peck.
5. Wood ashes, 2 pecks.
6. Saw-dust, 3 bushels.
7. Malt dust, 2 pecks.
8. Peat, 3 bushels.
9. Decayed leaves, 3 bushels.
10. Fresh dung, 3 bushels.
11. Chandler's graves, 9 lbs.

"With the exception of chandler's graves salt was decidedly the best of those used. On a trial of compounds, the combination of salt and soot was the best. The substances were mixed in the following order, and the same quantity of each employed as when used singly:

"No. 1. Salt and lime.
2. Salt and lime and sulphuric acid.
3. Salt, lime and peat.
4. Salt, lime and dung.
5. Salt, lime, gypsum and peat.
6. Salt and soot.
7. Salt and wood ashes.
8. Salt and saw dust.
9. Salt and marl dust.
10. Salt and peat.
11. Salt, peat and bone dust.
12. Salt and decayed leaves.
13. Salt and pearl ashes.
14. Salt and Chandler's graves.

"Perhaps this superiority may be accounted for by the quality of saline substances to attract moisture from the air; for those beds where salt had been used were visibly and palpably moister than the rest, even for weeks after the salt had been applied; and the appearance continued until rain fell, when of course the distinction ceased. In several instances the crop of the land failed altogether, except on the part where the salt was applied."

In Hindostan and China, all the land on the coast is regularly treated with sea-water; and they depend solely on this management for the increase and goodness of their rice crops. In Poland, salt is extensively used in the tillage of the land.

Many valuable communications on the use of salt as a manure have been made to the British board of agriculture. I may be allowed to mention two further experiments made on this subject.

To show the effects and advantages of salt properly applied to vegetables, the gardener of Lord R. Manners made the following experiment, in an extremely dry summer, upon a bare piece of pasture land out of which the cattle had been taken for want of grass. He marked off four places, each of which was watered for nine successive nights in the following manner: the first with one gallon of spring water; the second with one gallon of the same water, containing one ounce of common salt; the third with the same quantity of water and two ounces of salt; and the fourth with the same quantity of water and three ounces of salt, which gave the following effects:

The grass in the second place grew more abundant and of a darker green than in the first; in the third place it grew only by spots; for part of it was killed where the greatest quantity of water fell; and the fourth was quite killed, for a greater compass than the third; by which it appears that an ounce of salt in a gallon of water had a better effect than the water alone; and that three ounces of salt mixed in a gallon of water was more than the grass could immediately receive, but the fourth place, in the ensuing spring was the most fertile of them all.

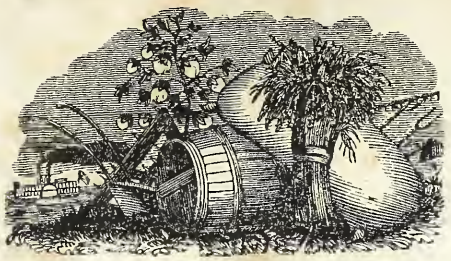
The other experiment I shall notice is related by Dr. Holland, well known by his agricultural survey of Cheshire.

"After draining a piece of sour rushy ground about the middle of October, he ordered some refuse salt to be spread upon a part of the land at the rate of eight bushels to the acre, and in another part sixteen bushels. In a short time vegetation disappeared totally; and during the month of April following not a blade of grass was to be seen. In the latter end of the month of May a most flourishing crop of rich grass made its appearance on that part where the eight bushels had been laid. In the month of July the other portion produced a still stronger crop. The cattle were remarkably fond of it; and during the whole of the ensuing winter, (which is ten or twelve years since,) and to this day, the land retained and yet exhibits a superior verdure to the neighboring closes."

JOHN C. MATHER.

Schaghticoke, Feb. 8, 1843.

Alaany Cultivator.



WEDNESDAY, JULY 19, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

In connection with this paragraph, we trust our patrons and the friends of a Southern agricultural paper, will pardon us for *again* invoking their aid in extending our circulation. We are pioneers in this work in Georgia, and although we commenced under the most unfavorable auspices, we are gratified to perceive that our efforts are daily exciting increased interest on this vitally important subject, and we feel grateful to our numerous friends for the countenance and support they have extended. Much however as they have done, there remains much more to be done, and we therefore invoke the aid of our friends in still further extending our circulation. Let them make an earnest and zealous effort to have it read by every planter—in short, let every subscriber take it upon himself to get one other subscriber, and he another, and both the good which we desire to accomplish will be attained, while we shall be abundantly rewarded for our efforts in this important enterprise. We therefore ask every man who reads this paragraph, to make an earnest effort to get us *one* subscriber, and as many more as he pleases.

TO READERS AND CORRESPONDENTS.

MR. CUNNINGHAM'S PROPOSITION.—To such as desire to embark in agricultural experiments for the improvement of our soils and the system now generally adopted by our planters, the proposition submitted by Mr. Cunningham in his letter, which will be found on our first page, affords a fine opportunity. We sincerely hope he may find such a purchaser as he desires, and that the future numbers of this paper may be enriched with the result of their experiments, and the country consequently benefited. It is, indeed, a laudable enterprise, and if the same spirit could be infused into many of our planters who live neighbors, much good would be accomplished, both to the cause of agriculture and the general prosperity of the country. Let our planters therefore look to this matter, and let a spirit be generally excited among them, either by means of Agricultural Societies, or by a rivalry between immediate neighbors, and the good effects will be apparent at a very early day.

SMUT IN WHEAT—BOMMER'S SYSTEM.—We acknowledge, with much pleasure, the communication of "H." of Athens, which will be found in this number, on these two, to the planter, most important and interesting subjects, and we commend it to their consideration. The experiment with the wheat is certainly very satisfactory, and would seem to be almost conclusive; certainly so for this season in that particular location, however it might be operated on in other locations in other seasons. It is an experiment however easily made, and should engage, as we hope it will, the attention of every planter in the country.

We commend also to the reader's attention the remarks of "H." on the subject of Bommer's method of making manure, containing as it does a most important piece of information to all who may desire to test the value of this system, which is now exciting so much and such general interest.

We are wholy unable to answer the enquiry of "H." as to his Berkshire sow. May she not be too fat?

SUGAR BOILER.—Mr. A. GREENE has kindly furnished us with a communication giving a plan for a cheap boiler, which he has tested, and to which we take pleasure in calling the reader's attention. If they should not desire to use it in experiments for boiling corn stalks, it will be found, as Mr. G. truly remarks, to answer many valuable purposes on a farm.

The communications of Mr. FARRAR, and "A LOVER OF GOOD HAM," are well worthy of consideration, and if any of our readers can answer the enquiries of Mr. F., we would thank them to make our paper the medium of communication, as they are subjects in which all planters are to a greater or less degree interested.

FINE WHEAT.—Accompanying the subjoined note, was a specimen of as handsome wheat as we have ever seen grown in any part of the Union. We should be glad if the writer will furnish, for our columns, an account of the character of the soil, its preparation, time of sowing, reaping, and, last though not least, the yield—all which will doubtless be highly interesting to our readers.

GREEN COUNTY, July 8, 1843.

Messrs. JONES—Having an opportunity, I forward you a sample of wheat which is of my own culture, and I think you will readily admit it to be a fine grain, and if any wheat is worth fifty cents a head this is the kind. The wheat crop, which is valuable, has been unusually productive the present year, and though I sowed but one gallon lacking a pint, I am willing to show it against any other wheat (of this State,) either in quantity or quality.

In haste, yours, &c.

A PLANTER.

AGRICULTURAL SOCIETY FORMED.

We notice with much pleasure from the Madison Miscellany, that an Agricultural Society has been formed in Morgan county—a sign which we hail with much pleasure, as the dawn of a new era in the prosperity of Morgan county. There is no county in the State where the benefits of an improved system of agriculture will be more quickly perceived, or more lasting in its effects, than Morgan.

Scraped horse radish made into a syrup, is said to be an excellent remedy for hoarseness.

UTILITY OF LOCUSTS, CROWS AND BLACK-BIRDS.

The appearance of Locusts in many parts of the Middle States this season, in great numbers, has elicited the following communication from Gideon B. Smith, which we clip from the Baltimore Patriot.

"Mr. EDITOR—You have, no doubt, as well as many of your readers, heard much of the injury done by locusts wherever they have appeared. Some have even attributed to them the death of human beings, (all romance, by the bye, as they have no means by which they can cause death or any personal injury to human beings;) others say they kill the trees and shrubbery, &c. &c., but I have not seen one item of credit for the good they do; and that the account may be fairly stated, that a just balance may be struck, permit me to give you the other side of the ledger:—1st. The locust saves the farmer a vast amount of corn, &c. as food for pig and poultry—for, during the locust season, no pig in pasture, or turkey or chicken will touch corn, or any other food than the delicious locust. 2d. During the locust season, the crow and the black bird will not pull up the corn. It may not be known to your readers, but it is a fact, that these birds only pull up the corn for the purpose of getting at the grub worm, who would have cut it (the corn) at any rate, even though the crow or black bird had not touched it. Well, the crow and black bird being supplied with abundance of the papa or grub of the locust, as they emerge from the ground, will not touch the corn. True, the grub worm is left to perform his avocation, and as the crow and black bird have not lessened their numbers this year, the farmers will have to look out next year for terrible havoc from this enemy of corn, wherever the locust have appeared this year. These facts ought to prevent farmers from destroying crows and black birds. They only seek the grub or cut worm, and if they do pull up a few blades of corn, they do it only to get at the worm which would have cut them down at all events."

CULTIVATE SMALL FARMS.

The Wilmington (N. C.) Chronicle has the following very sensible remarks on this subject, which we commend to the attention of our planters.

There has lately been considerable emigration from New York to Virginia, mostly of agriculturists, who find their account in selling their own well ordered fields for a high price and buying Virginia lands which have become cheap solely from bad husbandry. Many of the farmers of Dutchess county, New York, have sold their farms for one hundred dollars per acre, and purchased farms in Virginia for three or four dollars per acre, which they expect to make in a short time as valuable as the lands they sold.

'One mode,' says the Baltimore American, 'by which the Northern farmers improve the wornout lands in Virginia is to make small farms. The system of large plantations in the Southern States has resulted in deteriorating whole tracts and districts of country. Bad tillage is an almost inevitable consequence of such a system. The farmer or planter who endeavors to make up for the loss of fertility in his lands by increasing the number of his acres, only extends the evil which he would escape from, and adds to the amount of his labor without securing a corresponding return of profit.'

There are truths here laid down which Southern farmers do not give proper heed to. When will they learn to cultivate less land and cultivate it well? The system now generally pursued is about as wise as would be that of a schoolmaster who should attempt to teach one hundred boys himself, or the scholar who should undertake to learn every thing. We believe our farmers begin to see the evil. The sooner they set about correcting it the better for themselves and the country.

GESTATION IN ANIMALS.—In a recent German publication of great research and accuracy, the period of gestation and incubation in nearly all the domesticated animals is given, from which we select a few.

Animal.	Shortest per'd.	Mean per'd.	Longest per'd.
Mare,	322 days,	347 days,	419 days.
Cow,	240 "	283 "	321 "
Sow,	109 "	115 "	143 "
Ewe,	146 "	154 "	161 "

According to the report of M. Teissier, of Paris, who had charge of the experimental farm established by the government of France, of 582 mares which received the male but once, the shortest period was 287 days, and the longest 419, making the extraordinary difference of 132 days.

The most satisfactory experiment with cows on record, is that made by order of Lord Spencer, in which the gestation in no less than 764 cows was carefully noted. From this it appears that the shortest period in which a live calf was produced was 220 days, but no calf produced at a less period than 242 days could be raised.—The longest period of gestation was 313 days. From Lord Spencer's tables, as given in the Journal of the Royal Agricultural Society, it appears that 314 cows calved before the 284th day, and 310 calved after the 285th day; so that the probable period of jestation in the cow must be fixed at 284 or 285 days.

LAND IN SIGHT.—We believe that there has not been a time, since the general tumble down of prices, and the consequent agricultural distress, when the prospect of relief was so fair as at present. Farmers have been gradually, but certainly, surmounting their difficulties, and already they begin to breathe more freely. Driven to retrenchment and economy, what at first seemed an evil, is found to have been a positive good to all classes of society; and if the severe lessons the community have been taught, have their proper effect, we shall find many days of prosperity are yet before us. Debts heedlessly contracted, and without any rational expectations of meeting them, were the great cause of our personal or individual difficulties. The farmer has been slowly working his way out of these; and now better prices for his produce is coming to his aid, to complete the work. We would not intimate that the prices of 1837 are to be expected. They ought not to be desired, as they are inconsistent with a healthy and safe condition of things; but every thing indicates a gradual restoration of confidence, and prices that will be remunerating. We now, as a nation, sell more than we buy; our manufactories are getting into successful operation; new markets are opening for our agricultural products; specie, instead of gewgaws, is flowing in upon us; money is becoming plenty for those who have any thing to purchase it with; and there is a general feeling that the "dark day" is at last passed. We have only to avoid the errors of the past; to see our way clear before us; and as a nation or as individuals, to purchase nothing we do not need, and to pay down for what we do purchase, and we may reasonably hope, that if we do not become rich, we shall not be obliged to incur the disgrace of repudiation.—*Al. Cult.*

THE WORKING MECHANIC.—We cannot say too much in behalf of the working mechanic, who constantly is striving to make himself known, not only in becoming a proficient in his business, but who is every day raising himself to eminence by the course of his habits. A young man who has nothing to depend upon but his character and the labor of his own hands, for his elevation in the world, can, notwithstanding, arrive to the highest pitch of greatness, to the most elevated ranks in the community, and not unfrequently to the highest grade of national honor. And while we remark thus, we are happy to place to the credit of the mechanic, the fact that he ranks with that class of citizens who are the most likely, with judicious management, to become the welcome possessors of American popularity in every grade and form it assumes. Roger Shermam was once seated upon the shoemaker's bench, with his lap-stone upon his knees, and it was there, doubtless, that he first ruminated upon his first adventures. Are you a young mechanic? Determine, at once, to trace his history, and resolve to make yourself a greater man even than Roger Sherman.—*Farm. and Mech.*

FACTS FOR COTTON PLANTERS OF GEORGIA.—Will not the planters of Georgia encourage the use of bagging made from Cotton? Listen to these facts and decide for yourselves.

The cotton crop of 1839, by the published statistics, was from Georgia 163,000,000 pounds. Averaging the bag at 400 pounds, this made the crop 407,500 bags; this required, at 5 yards per bag, 2,037,500 yards, which at 20 cents per yard is $407,500. If the bagging made from cotton be used in place of *hemp*, every dollar of this money is retained in the State; whereas with the use of hemp, every dollar is carried out of it, except the small items of transportations and commissions. For safety sake we may say that $300,000 of this amount is taken away from the State entirely.

Again, to manufacture this bagging, each yard requires two pounds of raw cotton, which makes an amount of 4,077,000 pounds. Now if we use *hemp bagging*, we add just this amount annually to the *supply* from the crop for manufacturing purposes, and it tends to diminish the demand just so much. Suppose we convert it into bagging, we furnish a new *demand* for that amount; in other words, we withdraw from market that amount, diminish that portion of the supply—reduce the crop so much, which at 400 pounds per bag, is 10,192 bags, and thereby *increase* so much the *demand* for our cotton. In addition to the large amount of cotton thus consumed, there is also a considerable quantity converted into rope and twine. Will not the farmers study these facts and take the hint?—Read this article again and see how you like my suggestions. May not we reduce the price of bagging to 16 or 17 cents, if we encourage entirely our own manufactures in making it, and save commissions, profits and freights now made by commission merchants, and ships and steamboat owners. PUTNAM.

Southern Recorder.

LABOR.—Whence originated the idea that it was derogatory to a lady's dignity, or a blot upon female character, to labor? and who was the first to say, sneeringly, "Oh, she works for a living?" Surely, such ideas and expressions ought not to grow on republican soil. The time has been, when ladies of the first rank were accustomed to busy themselves in domestic employment. Homer tells us of princess who used to draw water from the springs, and wash with their own hands the finest of the linen of their own respective families. The famous Lucretia used to spin in the midst of her attendants; and the wife of Ulysses, after the seige of Troy, employed herself in weaving until her husband returned to Ithaca. And in later times, the wife of George III. of England, has been represented in hemming pocket handkerchiefs, while her daughter Mary sat in a corner darning stockings. Few American fortunes will support a woman who is above the calls of her family; and a man of sense, in choosing a companion to jog with him through all the up-hills of life, would sooner choose one who had to work for a living, than one who thought it beneath her to soil her pretty hands with manual labor although she possessed her thousands.—To be able to earn one's living by laboring with her own hands, should be reckoned among female accomplishments; and I hope the time is not far distant when none of my country women will be ashamed to have it known that they are better versed in usefulness, than they are in mental accomplishments.—*Selected.*

TO CURE A SNAKE BITE.—Mr. R. who has lived many years in the South where rattlesnakes have ever been exceedingly troublesome, causing frequent and sudden deaths, reports the following as a sovereign remedy for the bite: Put about a tea spoon full of the *Nitrate of Potash*, (*Saltpetre*) into warm milk, or when this is not convenient, into water, and after it is properly dissolved, let the patient drink it and relief will soon follow. This is perfectly *Homoepathic*, or in a little more learned style, *similia similibus curantur*, or in plainer style, "a hair of the dog will cure the bite.—*Tenn. Ag.*

HORN DISTEMPER.—A "Practical Farmer" in the Boston Cultivator, while he admits that the application of spirits of turpentine is good, asserts the use of hot brimstone as still better for the horn-ail. He puts one spoonful, boiling hot, into the cavity just between the horns.

GOOD FARMING.—"Sambo, is your master a good farmer?" "O yes, massa fuss rate farmer; he make two crops in one year." "How is that Sambo." "Why, he sell all his hay in de fall and make money once; den in de spring he sell de hides of de cattle dat die for want of de hay, and make money twice."

AUGUSTA MARKET.

TUESDAY P. M., July 18.

Cotton—Since our notice of the market in our report of the 4th, the business amongst our cotton dealers has been to a very limited extent.—The receipts have been very trifling and the stock on hand is very much reduced. We give the following as the present selling rates, viz:—inferior to ordinary 4½ @ 5, middling to middling fair 5¼ @ 6, fair to good fair and choice 6¼ @ 6¾ cents.

Money—Checks on New York, Philadelphia and Charleston cannot be had at less rate than ¼ ℔ cent premium. Central Bank notes continue to improve, and sales have been made as low as 7 ℔ cent discount. State 6 ℔ cent Bonds would bring 75 cents, and 8 ℔ cent Bonds 92 @ 93 cents.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., AUGUST 2, 1843. No. 16.

COMMUNICATIONS.

UNION POINT, GREENE CO., GA., July 28th, 1843.

Messrs. EDITORS—I have noticed in the 15th No. of the Southern Cultivator, an article over the signature of "A Lover of Good Ham," setting forth the necessity of our raising our own bacon; and though I agree with him in the first and second instances, viz: that we *should* raise our own pork, and that the Georgia public are grievously imposed upon by drovers in the article of "Berkshires," &c."—still I cannot agree with him as to the fact, that we have no pure blooded Berkshires in Georgia. It is true that the country is flooded with a spurious breed, *purporting* to be Berkshires, which are in fact but a remote *cross* of that breed. I fully concur with the writer of that article in censuring the cupidity of the western drivers in thus palming a mixed breed upon their neighbors, and in deprecating the credulity of the too unsuspecting Georgians in suffering themselves to be thus imposed upon. But there are, nevertheless, among us some of the stock as pure as any to be found in Berkshire county, England. Col. John Bonner of White Plains, in this county, has a choice lot of about twenty or twenty-five breeding sows, and three boars, of the "simon pures." I have had the pleasure of seeing his stock once or twice, and can assure "A Lover of Good Ham" that there are animals among them whose hams, if we may judge from their beautiful proportions, would tempt his appetite even if he was unusually fastideous. But as he may want proof, I will give the reasons why I believe them to be the pure blooded Berkshires: First, they excel any hog I ever saw in beauty and symmetry of form, tractable disposition, and capability of fattening; second, they have all the marks attributed to the pure bloods by breeders both in this country and England; and thirdly, *because several of them came from Berkshire county, England;* and of those not imported, he has full and authenticated pedigrees, running back to the imported stock, from such men as C. N. Bement, A. B. Allen, and Messrs. A. & G. Brentnall; men whose names are a sufficient guarantee for the truth of their statements. These facts I received from Col. Bonner himself, and I presume he will substantiate them if called upon. I have heard of other lots of Berkshires in this and one of the adjacent counties, but these I have *seen*, and I am fully convinced that if there are any pure blooded Berkshires in the United States these are.

But I am making this communication longer than I intended. My design was simply to convince your correspondent that he was mistaken in the fact assumed, viz: that all the hogs purporting to be Berkshires, in Georgia, were a mixed breed. By the way, Messrs. Editors, would you not be conferring a favor upon the farming community generally, if you would request of Col. B. to give to the public, through the medium of your paper, the result of his experience in rearing Berkshires; his manner of rearing, fattening them, &c.; their adaptedness to our climate; together with such other facts concerning them as may make their merits more extensively appreciated? I am clearly of the opinion that all who will try them, (I mean the pure bloods,) will be convinced that it is not "a multicaulis speculation."

Truly yours, J. M. G.

THE IMPROVED CULTURE OF COTTON.

Messrs. EDITORS—In looking over the 2d No. of your very neat and most excellent Southern Cultivator, a few days since, I observed an extract from a paper of mine, "upon the Improved Culture of Cotton," taken from the Albany Cultivator, of February last. At your permission, gentlemen, I avail myself of the earliest leisure moment from the duties of my profession, to correct a most erroneous impression, which I conceive that extract, in its present isolated position, is calculated to make upon the minds of your numerous readers. That extract, embracing as it does simply the modus operandi of the system of culture by which my cotton was grown the last year, which, together with the caption—"*How to make a large Cotton Crop*"—placed this improvement, and my object in the time, labor and trouble sacrificed in its accomplishment, in rather a ridiculous light before the sober and reflecting planter. Such planters, and their influence is beginning to be felt in our country, are disposed to look upon and hail the appearance of the Southern Cultivator, as the harbinger of better days than those of the *multicaulis, multibolis, and fancy stock humbug*, the pestiferous influence of which has swept over our land like an Egyptian blight. Such men are the patrons of light and knowledge in agriculture, they reason from cause to effect; give them the truth, the simple and whole truth, with all the conditions of any improvement, and they act upon the impulse of a wise and proper reflection. Their primary object is improvement, their views are liberal, and their motives patriotic. Thus in the exercise of a purely unsophisticated judgment, in determining the merits of a great national agricultural improvement, however brilliant the success in the end accomplished. They coolly and dispassionately take up the premises, and if they discover there a deep laid and broad basis, sufficiently immoveable to sustain the superstructure, though infinitely beyond the ken of even previous imagination, they will accord to it a most cordial approval. There is a presumptive evidence, at least, which the mind of the honest and generous hearted planter recognizes in the fact, that science is the governing principle here, the improvements of which upon the destiny of man, within the last half century, have accomplished more than all the *brute force* of the previous fifty centuries of the world's age.

Do not suppose me, gentlemen, ambitious to secure the precipitate credulity of a single planter, in the advantages of this improvement; all that is asked for it is, an *attentive* and *patient hearing* and a *fair trial:* to such planter reward is certain, and to such only. In collecting and grouping together these leading principles in the science of agriculture, so prominently and admirably held forth by Davy, Liebig, and the Cultivator, (Albany,) and in adjusting them to the economy and great ability of the cotton plant, let me assure you, gentlemen, I have been actuated by a higher and a holier motive than the sordid object, in the abstract, of "a large cotton crop!" This is certainly the result, and, in part, the planter's reward, which, however, I have ever regarded as the least interesting feature of the improvement. In its proper place, in my first paper, you may observe, that my object in these experiments has not been to augment the crop of cotton, either per hand or per the aggregate, already too great, but by an entirely new and improved system of culture, predicated upon the principles of a scientific and enlightened policy, to curtail the immense capital engaged, under the destructive system of the country, in its production, to one-third its present enormity. If I shall succeed in demonstrating this fact, my determined object, which my experiments the past season have more than realised, I shall have accomplished yet another step in this interesting improvement, and that not the most important.

Again, gentlemen, you will not fail to observe, nor will the merest tyro in the profession of agriculture, that the land thus treated, (as per detailed) after yielding the handsome reward to the industry, care and perseverance of the planter, of some 3000 to 5000 pounds of a superior staple per acre, will be improved by the operation in the ratio of some two or three hundred per cent upon its natural state. The soil thus

improved, the primary object of the system will be found the next year, superiorly adapted to the culture of corn; requiring simply the surplus cotton seed of the previous crop, with the same treatment otherwise, to insure a yield of 50 to 75 bushels per acre. The treatment of the succeeding two years, first in small grain, giving an equally large yield, and last, which completes the cyclus of rotation, to lie one season in the state of fallow, will each add greatly to the improvement of the soil. I have neither time nor space at present to enter more minutely into this most interesting branch of the subject, which sketch, however, will serve to illustrate my object in the institution of these experiments.

A short reply to your editorial commendation and I have done. It has not appeared surprising to me, gentlemen, that the result of my experiments should "seem extravagant" to you in your office, when I have seen planters, men too of experience and extended observation, from Baker county in your own State, and others from the rich alluvial valleys of the Chattahoochee, and the great Mississippi, while standing in the midst of my cotton, to express even greater reluctance in according their assent, though looking upon the well proportioned weed, yielding its thousands per acre. An optic entertainment this, infinitely more interesting than the rapids of Harper's Ferry, or their counterpart, Jefferson's Rock, which that great man declared to be worth a voyage across the Atlantic. N. B. Cloud, M. D.

Alabama, July 15, 1843.

P. S. You will probably be told, gentlemen, by some ad captandum planters, whose speculative temperaments have induced them to grasp at the "golden fleece" with impure hands, "that they have tried this system and it will not answer." Ask such men if they have complied with the conditions, and believe them not. I will here, in a very few words, inform you, and the friends of improvement, that I have cotton now growing upon pine land, a fair experiment, the present very unfavorable season, treated precisely to the letter as detailed in No. 2, that was topped on the 10th inst. six feet high, and so entirely interlocked the wide way as to forbid the further use of the horse hoe or sweep.—Upon a single stalk of this cotton, and it not better than others around it, I counted on the same day, (10th,) upwards of 300 bolls, blooms and squares—they literally hang upon the limbs in tresses—and this cotton has yet 75 days to mature. Think you the same success may not be attained in Carolina and Georgia? I tell you that the ingenuity and industry of the American farmer's sons, attained by the stern maxim of Roman perseverance, 'Nil desperandum, possent quia passe videntue," may, under this system, grow the same cotton and corn upon the poor, piney barrens of Edgefield and Richmond.

If there is a man who may eat his bread at peace with God and man, it is that man who has brought that bread out of the earth by his own honest industry. It is cankered by no fraud—it is wet by no tear—it is stained by no blood.

SMUT IN WHEAT.

Stanfordsville, Putnam Co., July 28, 1843.

Messrs. Editors—Your paper of the 19th inst. has just come to hand, in which I find a communication from your correspondent "H." of Athens, giving some account of the benefits resulting from soaking seed wheat in a solution of bluestone or strong brine, and rolled in slacked lime, to which I wish to add my experience. And I will here state, that the benefits I have enjoyed by soaking my seed wheat in a solution of bluestone have been derived from reading agricultural papers—my advantage from this one piece of information has been worth more to me than all the money I have ever paid for agricultural papers.

Year before last I soaked 15 bushels of my seed wheat in a solution of bluestone, and sowed it in a field as far as it would go; there being 6 or 8 acres of the field left, which were sown with the same kind of wheat, the land in about the same order, and the wheat equally as well cleaned, but had not been soaked. The result was, the wheat that was soaked was of good quality and clear from blast or smut; that part of the field sowed with the unsoaked wheat, had a considerable quantity of smut in it. I soaked my seed wheat again last year in the same kind of solution, and have a nice crop of wheat with not a grain of smut in it that I have seen. I did not roll my wheat after soaking in lime or any thing else, and several of my neighbors tried the experiment of soaking their seed wheat last year with entire success.

The quantity of bluestone used in this settlement is one pound to every five bushels wheat, and the plan has been to put the wheat in soak in the evening for the next day's sowing; reserving the water to put the next wheat in, and then add enough more water with its proportion of bluestone to cover the wheat. The best plan is to dissolve the bluestone in a small quantity of hot water, as it is hard to dissolve in cold water. If the weather should become wet and any of the soaked wheat not sowed, it may be spread in an out house without any injury till the ground gets in the right order for sowing again. I soaked some of my seed wheat last year 6 or 8 days before it was sowed. I have no doubt but rolling the wheat in lime after it is soaked is an advantage, especially when the seed wheat is not as thoroughly ripe as it should be, or the ground the least out of order, and this when it is too wet to be perfectly friable.

I would advise all wheat growers who are troubled with smut, to try this experiment or a similar one. The cost of a trial is but trifling, as bluestone costs only 20 to 25 cents per pound.

In concluding this communication, I do most sincerely advise all wheat growers to have their seed wheat thoroughly ripe, and then effectually cleaned with a good seive, (after being fanned,) letting all the small grains pass through the seive, and take all the light grains that rise on the top off with the hand. Should there be any cockel in the wheat, by using a seive of the right description, it will in a few years be entirely eradicated.

I am, sirs, yours respectfully,
John Farrar.

Wilkes County, Ga., July 17, 1843.

Messrs. Jones—I again address myself to my brother farmers, and would like, if I could call their attention to several things of importance to them which, I fear, are often neglected.

1st. The importance of taking better care of their stock. I think after the severe lesson they learned last winter, they will see the necessity of providing more and better provisions for their stock than has heretofore been customary. Every farmer should have comfortable shelters for all kinds of stock, and provender enough to keep them not only alive but in good order.—Shelters for cattle should face the south, and be boarded up on the ends and on the north; the roof should slant to the north, so that the cattle may get the benefit of the sun. There should be a ditch cut large enough for the rain to run off. Salt should always be kept in reach of the cattle, so that they can get at it as often as they want. A good mixture for cows is, half salt and half ashes.

2d. Farmers should make all the manure they can. They should save everything—soapsuds, ashes, chamber ley, dish-water, dead animals, leaves, hair, and every thing that can possibly be made into manure. It should be applied to the land every year if possible, and it is better to manure one acre well, than five poorly and sparingly.

3d. *The Cultivation of Corn.*—I should like to see a discussion in your paper in regard to this subject. I think the old system of culture may be greatly improved, as I am of opinion it should not be plowed deep, if at all, after it becomes breast high. Plowing at this time cuts the roots, thus forcing the plant to form new ones, and of course checking the growth. I hope your subscribers will give their opinions on this subject, as it is one which calls for discussion, and as almost every one has a different way of cultivating this plant. I will close by saying that *manure* is the sheet anchor of the farmer.

I remain your friend, A. O.

Spaying Swine—I have seen several directions given for spaying swine; none however, I think, superior to mine, which is as follows: I have a crooked stick, in the form of the arm when half bent, about 18 inches long; to each end I attach a string, doubled, about 8 or 10 inches long, which I put in a noose over the hind legs, just above the hocks; hang them up head downward; tie the mouth to prevent squealing; let a boy stand at their back and hold the fore legs. I then with a sharp knife split the belly just between the hind four teats, sufficiently to insert two or three fingers of the left hand, draw out the pride, and cut it off with the knife in the right hand; then with a large crooked needle and waxed thread, sow up the wound in the following manner: stick the needle through from outside to inside, then bring out the needle on the other side of the wound, from inside to outside; cut off the thread sufficiently long to tie; repeat the same so as to make three stitches; then tie them, being careful not to draw the stitches too tight, and the work is done. I believe I can spay as many in a given length of time and with as little loss, as any man can any other way. John M. Johnson.

Hannibal, Mo., May 25, 1843.

Albany Cultivator.

Laziness travels slow and poverty thumps his heels.

FINE WOOL SHEEP.

Office of the "American Agriculturist," July 13, 1843.

To the Editors of the Spirit of the Times:

Dear Sir:—As you have expressed an intention of copying from our July No., in the "Spirit," the article on '*Fine Wool Sheep*," I desire to add a paragraph to it, showing the additional value it would be to the country to adopt the superior breed in question, in the hurry of writing, was forgotten at the time of publication. It was this:

Out of the twenty millions of sheep which are kept in the United States, I supposed eleven millions were shorn, producing 2¼ lbs. per head, making 24,750,000 lbs. of wool per annum. Now, by breeding the finer kinds of sheep, not only would the *value* of this large amount of wool be increased 9 cents per lb., making a gain to the country of $2,227,500, but the *quantity* also would be increased at least one pound per head, which reckoning the price at 30 cents only per pound (it is actually worth nearer 40 cents, low as wool now is,) would make another item of gain to the farmers, annually, of $3,300,000! Thus, by improving the *quality*, and at the same time adding to the *quantity*, the value of the wool then produced in the United States, on the *same food*, would be $5,527,000, an increase of more than 100 per cent; and this is but one among the many benefits proposed to the country, by adopting an improved stock, and an improved system of husbandry.

A. B. Allen.

—

FINE WOOL SHEEP.

Rambouillet Merinos.—Agricultural products of all kinds being so very low throughout the Union, it has become quite a desideratum on the part of the farmer, to know to what objects he can turn his attention, with the best prospect of realizing the surest and greatest profit from his land. We have thought, notwithstanding its unprecedented low price, that the raising of a superior quality of fine wool, especially on the hilly lands of the south and west, was now, and would continue to be, one of the safest and most lucrative branches of husbandry. We have accordingly so expressed ourselves from time to time in the pages of our journal, and we hope that our readers will not be impatient, if we continue to advert occasionally to this very important subject.

By the census of 1840, we see that there were, in round numbers, twenty millions of sheep in the United States. On account of the prevailing low price of wool and mutton for the past three years, it is generally supposed that there has been no increase among the flocks of the country, and that they are now about the same number as in 1840. As in this number, lambs as well as grown sheep are included, it will be fair to suppose that but little over one half, or say eleven millions, are shorn. The average product of fleece in these, we think we may be safe in estimating at 2¼ lbs., which would make 24,750,000 pounds of wool per annum. The average value of this is probably 21 cents per pound, which would amount to $5,287,500.—Now by producing a superior quality of wool, its value may be enhanced full nine cents per pound, which would be adding to the income of our farmers, no less a sum annually than $2,227,500, which in these times of pecuniary distress, would be felt as a very desirable and convenient increase to the earnings of agricultural labor.

Where a mild climate prevails, there is no doubt but that the increase of a flock after all the fixtures are prepared for its accommodations, will pay the expenses of keep and attention, and that the wool shorn from it will be clear gain. Sheep also are the best renovators of the soil; that is, by pasturing them upon poor or worn out lands, they will restore them to fertility sooner than any other kinds of stock: it therefore behooves the farmer and planter to consider, with these double objects before them, viz: the profits of agriculture and the improvement of the soil, whether they can do better as one branch of their business, than to keep 100 to 1000 sheep, according to the situation and the extent of their landed property.

Mutton being but a secondary, and wool the paramount object with the American farmer, the best animals to start with, or make improvements on those already on hand, are undoubtedly the Spanish Merino. And here we have to lament the great deterioration in blood and breeding, of those hardy and inestimably valuable flocks which were imported direct from Spain by Col. Humphrey and others, from the years 1808 and 1811. These had scarcely overcome prejudice, and got well planted among us, than our countrymen, true to their character, and despising pedigree and distinct breeds, and neither knowing nor caring for their value, and seized with the conceit that they could improve them by crossing, not only foolishly commenced mixing up these importations by coupling them together in all sorts of ways, thus making, to use a Spanish expression, a complete "olla podrida" (hodge podge mess) of the breeds, but in addition to this, as if it were not bad enough already, they must needs add by way of still further and more "scientific improvement," crosses of the miserable culls and offscourings of the open-fleeced Saxon flocks, imported by a band of mere mercantile speculators, in such numbers from the years 1824 and on.* But thanks to the good constitution, strength and fixed thorough breeding of the original Spanish Merinos, let the improvers do their worst, they could not wholly destroy them; and there are still large and valuable flocks scattered over the country, from which good ewes may be selected at a small cost, with which those disposed to go judiciously into the rearing of fine wool, may commence with the certainty of starting as near right as circumstances and a prudent economical outlay of capital will permit, and when with the use of pure breed, unadulterated Merino bucks, they may go on in the broad road of improvement, and be annually increasing the value of their flocks, raising the standard of quantity as well as quality of the wool produced, and thus adding greatly to the incomes of the sheep husbandmen.

Among those pure bred flocks from which bucks may be chosen, with a view of effecting this important purpose, that undoubtedly superior to all others, within our knowledge, in the United States, is possessed by Mr. D. C. Collins of Hartford, Conn. Travelling in Europe in the year 1839, and having his eye occasionally upon its Agriculture and improved stocks, among other things, this gentleman was struck with the marked superiority of the Spanish Merino, composing the celebrated royal flocks kept at Rambouillet, in France, about 40 miles from Paris. He accordingly determined to procure a small breeding flock, with a view of raising bucks to restore the fine woolled sheep of our country to their original character for strength of constitution, and weight of fleece, together with excellence of quality. The following year he obtained two bucks and twenty ewes from the best of the Rambouillet flock, and brought them over to this country. These he has continued to breed here with great success, and has now a fine flock of their produce, fully equal to the original importation.

On p. 171, Vol. 1, of the Agriculturist, we gave a short notice of these animals; but the subject of the production of fine wool in our country seems at present to be so important, that we have thought we could not do our readers a greater service than bringing the matter up again for their serious consideration. Understanding, therefore, that Mr. Collins intended shearing his flock on the 15th of last month, we started for Hartford, and arrived there on the morning of the day previous for the purpose of inspecting them in full fleece, and then in their naked forms, as also some flocks alongside of them, of what may now be termed the native Merino. Altogether we spent three days in our examination, taking samples of the wool, weighing the animals and their fleeces, and studying their forms, from the lambs just dropped, up to the full grown sheep of a mature age. The result of our observations, and the information we obtained, with respect to these Spanish Merinos from the royal flocks of Rambouillet, and the produce bred from them in this country, is:—

1. They possess as good constitutions, and are as thrifty and as hardy as any native or imported sheep whatever.

2. They attain a great age, have been known to reach 20 years, and may be depended upon as good breeders and wool producers till 12 or 14 years old.

3. They have large, loose skins, full of folds, especially around the neck and below it, on the shoulders, and not unfrequently over the whole body; the wool thickly covering its surface, the forehead, cheeks and the legs clear down to the hoofs, giving the fleece the appearance when shorn and spread out in its ample dimensions, of having been taken from the carcass of a huge buffalo, rather than so small an animal as the domestic sheep.

4. The fibre of the wool is very fine, quite equal to the best Merino in Spain, and is the very antipodes of that of which so much complaint is made by the manufacturer, of being harsh, dry, crispy and wiry. The fleece opens of a brilliant creamy color within, on a skin of rich pink, and is soft, glossy, wavy and very even over the whole body; is exceedingly close and compact, and has a yolk free from gum, and easily liberated when it comes to be washed, but which protects the wool from the weather, and keeps it free of the dead ends that are so objectionable, and that make so great a loss in the more open fleeces of the Saxons and their crosses. It becomes of the purest white when scoured by the manufacturer, and still retains its mellow, oily touch, so grateful to the handling of good judges. Its felting properties are beyond dispute, making it a choice material for the manufacture of fine broadcloths and cassimeres.

We are tolerably familiar with the Merinos imported direct from Spain, and the subsequent breeding in the United States, and we find the distinguished superiority of the Rambouillets over them, is in the size of their skins, enabling them to cut a greater proportion of wool. In their form they resemble the Paular Merinos, more than any other tribe of Spanish sheep that have fallen under our observation. They are also from one tenth to one fifth larger in carcass; are equally thrifty, hardy and long-lived; give more wool for their size, and of a better quality; and upon the whole, present a grander and more noble appearance. It is not contended that the Merinos of any tribe have the finished, full round forms of the English mutton sheep.—They have been bred for other purposes. Their flesh is reasonably good when made wethers, and killed at a suitable age, and their forms are susceptible of improvement, for in this particular we occasionally see them nearly equal to a South Down or Leicester.—*Amr. Agriculturist.*

The Sunny Side.—How much more pleasant it is to the pure heart to be good—to kindle the more gentle and noble feelings of our nature—than by misrepresentations, hints or dark inuendoes to break into long established friendship and disturb the good feelings of years of intimacy. In all our associations, commend us to him who ever presents the sunny side of life's picture to our gaze; he who has always a "pleasant word to speak," and is ever disposed to fling the mantle of oblivion over the foibles of erring man. Such a man we could wear in our "heart's core—ay, in our heart of hearts." But from the mischief maker, whose bosom is filled with a canker who knows no pleasure except that which torments others, "good Lord deliver us."

A Veteran.—The Journal of Commerce speaks of a horse driven into Wall street every day, which though forty-two years old, is as surefooted, sprightly and playful as a colt.

ON THE COMPARATIVE ADVANTAGES OF HERDSGRASS AND CLOVER AS GENERAL IMPROVERS OF THE SOIL.

GENTLEMEN—I should not have ventured to deviate from the rules of the Club, in submitting my views *in writing* on the subject of the comparative merits of Herdsgrass and Clover, as general improvers of the soil, but for the invitation to do so, which was given to me at the last meeting. With this apology, I shall proceed at once to the subject in hand.

That no extended system of improvement can be rapidly and successfully carried on, without the aid of the artificial grasses, as a general rule, will, I presume, be conceded by all present.

Manure, which is essential to the improvement of all soils, should be abundant on every farm, and every agent which aids in increasing the quantity or quality, without detracting from the fertility of the soil whence it is taken, is desirable, in proportion as it effects this object.—No agents of this kind, so susceptible of extended application, have yet been employed, as the artificial grasses. As food for stock, they constitute the cheapest, as well as the most nutritious; as covering for the soil, to shield it from the impoverishing effects of the frost and winds of winter, and the parching sun of summer, they constitute the most complete; as litter or soiling for stock, they are the cheapest, richest and most abundant; and as agents to prevent the gradual washing away of the soil by heavy rains, none have been found so effectual. So, that, whether we use them as food for stock, top-dressing for lands laid out to rest, or litter for our stables, farm-pens, &c. their value must be admitted. That they, or some of them, are in general essential to extensive improvement, will also be readily admitted; but the question of the comparative advantages of herdsgrass and clover, is one that admits of more doubt.—When land, and especially tobacco land, is to be cultivated on the three shift system, clover is certainly preferable to herdsgrass, for the reason, that it forms a more speedy and a more complete covering for the land, when laid to rest; the clover requiring one year only to arrive at maturity, while the herdsgrass requires several, to produce such a turf as is adequate to any great improvement. But when the four or five shift system is pursued, I have no hesitation in giving the herdsgrass the preference; and so far as the tobacco crop is concerned, I have never known it to fail on herdsgrass turf, well cultivated, while clover lots frequently fail entirely, from want of its necessary concomitant, *plaster*, or from the ravages of vermin or some other unknown cause. As a fallow for wheat, I consider the herdsgrrss totally unsuitable, on account of the difficulty of eradicating it, particularly on moist land—while the clover is easily destroyed by summer fallow. As a forerunner of corn, I consider the herdsgrass objectionable, on account of the difficulty of preventing its growth among the young corn, and the additional labor which it requires to reduce the strong turf which it forms; all which may be partially overcome by early working. But it is chiefly as a hay crop, and as a grazing grass, that I give this the preference to all other meliorating crops relied on in this country. Among the many errors maintained and exploded in the agricultural community, there is not a greater, than that a small stock in proportion to the size of the farm, or in other words, that the "*non-grazing* system" is essential to improvement.—Under the mode pursued by many in this country, of keeping a large stock, without the aid of the artificial grasses, this might seem plausible enough, but many enterprising farmers and planters have discovered, that just in proportion to the quantity of the artificial grasses cultivated, is the means of grazing and keeping stock, and just in proportion to these, is the improvement in the stock, the facility of making manure, and the consequent improvement of the land. My own observation has satisfied me, that the dung dropped by cattle running on land cultivated on the three and four shift systems, without the aid of the grasses, bears no proportion either in quality or quantity, to that from land laid down in herdsgrass or clover. As hay, heardsgrass has no superior, whether you regard the quantity or the nutritive qualities of the food, for every variety of farm stock, or the litter which it affords for the stables and farm-pens. ere the herdsgrass has the most decided advantage over clover, not only in the quantity and quality of the hay, but in facility of curing and preserving it from the effects of moist or rainy weather, or from heat and mould in the shock or stack. Another advantage is, that those who cultivate herdsgrass, can always obtain their seed at a trifling expense of time and labor, while, as every tobacco planter knows who has tried it, the clover seed must either be saved at a great expense of both time and labor, at a very busy season, or be purchased, and thus become annually a heavy tax. Another advantage of herdsgrass over clover is, that land once well turfed will remain so for years, while clover begins to decline after the second year. And again, clover is not only not valuable for grazing after the month of June, but actually deleterious to stock, and particularly to horses, mules and sheep, while the herdsgrass affords fine grazing for every variety of farm stock throughout the whole year, with the exception of those portions of winter when every species of vegetation is locked up with snow or frost. Farther, the herdsgrass when once sufficiently thick to form a strong turf, even on land really poor, will, in a course of years, restore it to tolerable productiveness; while on the same land clover will not grow sufficiently without the aid of manure, to produce any obvious improvement of the soil. More than twenty years experience has produced but little change in my views in regard to these grasses, except that I am now persuaded that a judicious system of grazing ought to go with them, hand in hand.—The long practice of seeding poor, thin and pipe clay flats, in herdsgrass, has satisfied me that there is scarcely any such lands that may not thus be brought, even to tobacco heart, and especially where they are occasionally inundated. And I have long known, and probably you all know, that there is no land which produces finer tobacco than the old herdsgrass meadow. But I have yet to learn that any such land, or any other poor land, has been restored to tobacco heart by the use of clover alone.

I have but recently turned my attention extensively to the cultivation of herdsgrass on Bluestone, having from one or two failures to get a good stand, erroneously supposed that the fault was in the soil. I have ascertained, however, from the experience of the two last years, that it only requires, on oat land, to be seeded thick, immediately after the land is ploughed and before a rain ensues, to ensure a good stand. And that the soft, sandy hills, on the west side of the creek, present at this time as good a stand as any close, moist soil not more thickly sown.

While I would most urgently impress upon our Club, the importance of sowing grass exclusively, and especially herdsgrass, I am far from wishing to disparage, or enter the lists against clover. For I am myself pursuing the three shift rotation, of tobacco, wheat, and clover; and so far, have much cause to be gratified at the result. There is much too, depending on the peculiar situation of the farm, character of the land, and other circumstances, to determine the planter as to the expediency of cultivating the one or the other. I would earnestly recommend both, but with my present views, founded on the experience of others, as well as my own, I am constrained to give my most decided opinion in favor of herdsgrass as a general improver; and in coming to this conclusion I have not lost sight of the benefits to be derived from either. For the value of any material or crop used on the farm for improvement to be fairly estimated must be considered in all the various uses to which it is applied; and in all these I consider the herdsgrass as adding to the resources of improvement, not even excepting the raising hay for market; for I doubt not that after abstracting the hay crop, the meliorating effects of the remaining turf, will richly compensate the owner for all the trouble and expense of preparation, seeding, &c.

In this part of the country, we have no available resources for manure but those derived from the farm and its appurtenances. We have no right to expect that marl, lime, plaster, poudrette or any other substance of foreign growth or manufacture can ever be obtained here sufficiently cheap, to justify their general and extensive use. It becomes us, therefore, to cast about for some other material to supply their place; and to do this, we must (and the sooner the better) look at home, and here we may, in some measure, help to check that constant drain which empties our purses for the foreign capitalits and brings no corresponding benefits to ourselves.

Vegetable matter mixed with animal and other substances, must ever constitute our chief resource; and there is no vegetable matter more valuable, and none can be raised in greater abundance for the purpose, than herdsgrass.—Our branch flats, creek bottoms, and lands subject to inundation, might be profitably employed in its production. If it escapes the water, it will furnish the stock with food, if inundated, it will furnish them with litter. My own most valuable resource this year has been the yield of an inundated meadow, mowed and regularly cured and stacked in season—furnishing a quantity of good seed, as well as an abundant supply of litter. I prefer the herdsgrass, however, for food, and the quantity and quality of the manure raised from the stock to which it is fed.

Let me now, gentlemen, urge some considerations in favor of the artificial grasses which ought to come home to the feelings and the taste, as well as the pride of our club. Is there not something humiliating in having our eyes, whenever we ride or walk into our fields, greeted with the yawning gall, or the more hideous gully? or meeting by the wayside, the kine of Pharaoh, who, having devoured all the miserable trash and weeds, which mar the beauty of our fields, are themselves just about to be devoured by the buzzards? How do these scenes contrast with the verdant grass springing up in all its vigor and luxuriance, and clothing our fields in its beautiful habiliments; with the cattle of a thousand hills grazing bountifully thro' the day, and returning home at eve laden with deposites richer than those of the *mammoth bank*, and laying their grateful tribute at the master's feet, and causing his table to groan under the teeming abundance of milk, butter cheese and beef?

This, gentlemen, is no ideal picture--it is in reach of every man who will adopt the cultivation of the artificial grasses, and avail himself of all the benefits which will result from their judicious and economical use.

Should doubts still remain after the interesting discussion of this subject had at our last meeting and what has come before us at this, they can only be solved by judicious experiments of our own, or observation of the experiments of others. Permit we to state, however, in conclusion, that there is one fact which ought to weigh with no little force on the minds of our Club, and that is, that we know no instance of a skilful and enterprizing farmer or planter who, after having gone fully into the cultivation of the artificial grasses, "has returned, like a sow that is washed, to her wallowing in the mire." And that we know no instance of a country in a high state of agricultural improvement, where the artificial grasses are not regarded as the main stay and the one thing needful.

With these views, gentlemen, I must close this subject, not, however, without expressing my regret that I have not had time to prepare something more worthy of my enlightened auditory and the interesting and important cause which has brought us together, and which it is

to be hoped each member intends, to the best of his ability, to promote, whether in his own immediate practice at home, or generally throughout the bounds of the Club.—*Southern Planter*

LEGISLATIVE AID TO AGRICULTURE.

The subject of legislative aid to agriculture is one of so much importance, that we feel ourselves justified in occasionally referring to it. It is one which should certainly be kept before the farmers of the state, now that the experiment made is in such successful progress, as the friends of agriculture should be anxious to ascertain fully the operation of the present law, that they may act understandingly when the question for its renewal or discontinuance shall come before them. That the legislature will be governed by the will of the people, and that their opinion of the matter should be fully expressed, no one can reasonably doubt. That the present enactment in favor of agriculture has operated most beneficially, we have as yet heard no one dispute. The prejudices of many against the measure; prejudices honestly indulged, and originating in former errors connected with similar aid granted, though on conditions entirely different, have been done away; and perhaps no legislative act of the last five years, can be named about which there is so little diversity of opinion among all classes, as respecting the one by which a pittance of the State's revenue is devoted to the encouragement of agriculture.

There can be no question that the true cause of the efficiency of the present law in favor of aiding agriculture, is to be found in that provision which renders it necessary that the farmer should help himself, before he was entitled to expect help from the State. Experience in all matters of a similar nature, has demonstrated that there is no way in which the interest of individuals can be so soon secured, as by connecting the prosecution of the object with personal contribution. By rendering it necessary that County societies should be organized, and should raise an amount equal to that to which they were entitled from the State, the subject was brought home to the agriculturist, and the benefit he was to receive made dependent on his own exertions.

There has been a strange opinion prevalent on this subject of aid to agriculture, which was that while all other classes were receiving more or less aid or protection from government, the agricultural part alone were to be left to their own resources. The merchant sails his ships and carries on his trade under the fostering protection of the nation; the manufacturer keeps his hammers and spindles active through the same influence; but it is expected that the farmer, he who furnishes freight for the one, and sustenance for all, shall go on with no encouragement from the public, while he bears the burden of taxation, and keeps the wheels of that government by which he is neglected, moving. This State has appropriated forty thousand dollars, or eight thousand dollars per year for five years, for the benefit of agriculture; and what is the result? We see associations springing up in every county to avail themselves of the grant. Public opinion is directed to the importance of agriculture, and a spirit of emulation and improvement is excited. Cattle Shows and Fairs exhibit to farmers the vast difference between good and bad implements, superior and inferior stock, and by bringing farmers in contact with each other, do away those feelings of distrust and distance, which are too often operative where seclusion and confinement to the farm prevail.

There is another reason why the State should lend its aid to agriculture, which is yearly becoming more efficient, and more deserving of attention. Scientific and practical improvements in agriculture, are not a less decided common public benefit, than in any other department of life; and while no one grudges the sums expended for the purposes of education, as such, by the State, the farmer can fairly demand the extension of those benefits conferred at the present time by the application of science to agriculture, through the influence of societies formed and fostered by the aid of the State. The sum demanded is so trifling, compared with the object in view, that it is surprising the granting the required aid should have encountered so much opposition; and it can only be accounted for by supposing that the objections had reference rather to the manner in which aid was to be given, than to the granting of the aid in itself.

The money drawn from the treasury to aid the cause of education, has for its object the elevation of the masses by the extension of knowledge, or the means of acquiring it, to all; it is to teach them their rights and their duties, and the best means of fulfilling them; to erect and point out to them a higher standard of moral and intellectual power than the one their fathers were accustomed to contemplate. It is to aid in the extension of knowledge most essential to all, that the farmer claims the aid of legislation. That alone seems adequate to spread the rich results which the labors of science, and the experiments the principles developed have produced, before those who are the most interested in them. No matter what the subject may be, if it is one of common benefit, commerce, manufactures, education, agriculture, all have a right in proportion to their importance, and without infringing on the rights of others, to look to legislation for aid. If there is a pursuit more ancient, more honorable, or more deserving of public aid than agriculture, it is still to be pointed out; if there is one in which the same sum will produce greater or more beneficial results, it is still to be shown.

We trust that in the examination of this subject, no person, certainly no farmer, will allow any considerations except such as spring from a regard to the public welfare, to have for a moment a place in his bosom. All party feelings, all narrow and contracted views, all sectional or personal jealousies, should be eschewed at once and forever. It is a subject in which all are interested, for the cultivation of the soil and its products, constitute the base of prosperity to all classes. Let the operation of the present law, in all its bearings and its consequences, be well and carefully weighed; and when the time arrives for its re-enactment, with such alterations as experience may suggest, we cannot believe that any enlightened legislator will be found among its opponents.—*Alb. Cultivator.*

BLIGHT OR MILDEW IN WHEAT, COMMONLY CALLED RUST.—The period of maturity most proper in every respect for the cutting of wheat, has long been a subject of discussion among practical farmers, both in Europe and this country. So long as wheat was threshed by hand, it was found necessary to let it ripen fully. But since threshing machines have been generally introduced, this difficulty has passed away. It is now, how does early cutting affect the weight and quantity of the grain, and quality of flour. In the summer of 1842, most of the pieces of wheat in my neighborhood were struck with rust. I had a small piece of winter wheat that was almost red with rust, and it was yet in the milk, the least pressure with the thumb and finger would reduce the berry to a pulp. I had the cradle put in and cut. Some of my friends said it would make good fodder, and others inquired if I was cutting for the straw, but I was firm in the belief that I should save the grain. I let it remain in swathe until the straw was quite dry, then bound and put in stock with cap, and let it stand ten days to cure well, then drew it in and threshed with machine, cleaned up and had 20 bushels and 8 quarts per acre, weighing 56 lbs. to the bushel, and makes good flour, while most of the wheat that was affected with rust and left to ripen was almost or quite a failure. Perhaps the most universal rust or blight ever known is that which fell upon almost every acre of wheat in the northern parts of Indiana and Illinois, in 1840; upon several thousand square miles of a rich soil, as ever the sun shone upon, not one acre in ten was worth cutting; early and late sown, and upon every grade of soil, all was affected. Had the farmers of those wheat-growing States, cut and cured their grain in a similar manner, as soon as the disease made its appearance, if it was so far advanced as to be fully in the milk at the time of the attack, the saving to themselves, and the country at large, would have been immense; for if left to stand and fully ripen, as in that case it was, it is not worth cutting; when cut in the proper time, the stem or stalk contains as much elaborated sap nearly as the perfection of the grain will require; but if this is allowed to escape as it will, if the disease progresses, the berry will be deprived of its proper nourishment, and the grain will be worthless. If the grain has so far advanced as the raw state, so called, when the attack is first seen, and cut immediately, the grain will be as plump and as heavy as if the rust had not made its appearance. THOMAS LANE.

Marcy, March, 1843.

New York Farmer.

SEEDS.

Every farmer should, as far as possible, raise his own seeds, as he will not only thereby avoid a considerable item of expense, but will, if there is proper care and skill used in their production, have such as may be depended upon.—There are but very few of the cultivated vegetables and fruits, of which the seeds can be depended upon for the production of plants like the original, if other plants of the same family are permitted to blossom in the immediate vicinity. The cause of this is to be found in the effect which the fertilizing dust or pollen of flowers has on the germs or seeds, when different varieties are placed so near each other that intermixture takes place. It is in fact a real cross, as distinct as that of animals, and with as decided results. For the philosophy of the matter, we must refer to Professor Lindly's work on Horticulture, or Roget's Animal and Vegetable Physiology. Every farmer or gardener is aware that apples or peaches raised from seeds, are rarely like the fruit that produced them; that melons, squashes, &c., are apt to mix or degenerate, and that where several varieties of corn are planted together, intermixture is certain to take place. We had a fine opportunity of verifying this last result two years since, when we cultivated some twenty four or five varieties of corn in a field, as an experiment, to test the period of ripening qualities, &c., and the singular manner in which the different colors and qualities were blended, was both curious and instructive. In purchasing seeds from our agricultural seed stores, farmers are very frequently disappointed in the plants produced, a disappointment frequently owing to there not having been sufficient care taken while growing the seeds, in preventing the possibility of intermixture. Beets may be mentioned as an instance of this, as perhaps there are more failures in these seeds, and more instances of degeneracy with these than any others. It may be considered a rare instance of good fortune, if the man who purchases blood beet seeds, does not find, when they grow up, that his roots are a coarse, unpalatable article, of some shade between red and white, or perhaps yellow, and utterly unlike what he expected. We have found that this result has been prevented, if, when the seed beets are set out, and the stalks shoot up, we examine them, and select for preservation those plants, the stems of which are of a deep red color; or when white or yellow are desired, selecting the purest of the kinds, and destroying the others at once. Planting for seed at such distances that the intermixture will not take place in the way pointed out, will also secure the seed from deterioration; but this, except with professed seed growers, is not always convenient. The best way to keep the varieties of early cucumbers, summer and other squashes, &c., when grown as farmers usually produce

them in their gardens, is to allow those that set the earliest, and of course nearest the root, to remain for seed. Experience shows that these are less liable to crossing and degeneracy than those that set later, owing, perhaps, to the number of other blossoms being smaller, and the danger of the fecundating pollen being transported by flies, bees, &c., proportionably less.—One thing is clear, seedsmen cannot be too careful as to the quality of the seeds they put in the market. Carelessness as to the kind, or the purity, has an inevitable tendency to destroy all confidence in these necessary establishments, without which it is scarcely possible agriculture should reach the elevated position we trust it is yet destined to reach in this country.

Albany Cultivator.

RULES FOR BREEDING.

Although there is a great discrepancy of opinion upon some portions of the mysterious art of breeding, the following precepts, from the pen of one of the most distinguished anatomists in Europe, Professor Cline, are, we believe, universally received as established doctrines amongst those who have the best right to know; although dame nature sometimes amuses herself in setting at naught the most ingenious theories of philosophers.

When the professor objects to large bones he must not be misunderstood. From the bone and muscle strength is derived, and, we presume, the greater the quantity of either, the greater will be the strength of the animal; but the quantity is not always to be measured by size; indeed, as Mr. Cline remarks, they are generally found in an inverse ration. In some animals a much greater quantity, both of muscles and bone, is condensed into a much smaller space than in others, and this constitutes the great physical difference between the Arabian and their descendants, commonly styled "blooded horses, and those of other descriptions. The ivory of the blooded horse will always outweigh, though it will never out measure, the open, porous bone of the cart-horse. But where the density of fibre is equal, size will indicate quantity, and therefore strength. With equal quality of bone and muscle then, the largest animal will always be the most powerful. With this commentary, we give to our reader the Professor's opinions [from Mr. Bott's "Southern Planter,"] upon the following subjects:

"Muscles.—The muscles and tendons, which are their appendages, should be large; by which an animal is enabled to travel with greater facility.

"The Bones.—The strength of an animal does not depend on the size of the bones, but on that of the muscles. Many animals with large bones are weak, their muscles being small.—Animals that were imperfectly nourished during growth, have their bones disproportionably large. If such deficiency of nourishment originated from a constitutional defect, which is the most frequent cause, they remain weak during life. Large bones, therefore, generally indicate an imperfection in the organs of nutrition.

"On the Improvement of the Form.—When the male is much larger than the female, the offspring is generally of an imperfect form. If the female be proportionably larger, the offspring is of an improved form. For instance, if a well-formed large ram be put to ewes proportionably smaller, the lambs will not be so well shaped as their parents; but if a small ram be put to larger ewes, the lambs will be of an improved form.

"The proper method of improving the form of animals consists in selecting a well-formed female, proportionably larger than the male.—The improvement depends on this principle: that the power of the female to supply her offspring with nourishment is in proportion to her size, and to the power of nourishment herself from the excellence of her own constitution.

"The size of the fœtus is generally in proportion to that of the male parent, and therefore when the female parent is disproportionably small, the quantity of nourishment is deficient, and her offspring has all the disproportions of a starveling. But when the female, from her size and good constitution, is more than adequate to the nourishment of a fœtus of a smaller male than herself, the growth must be proportionably greater. The large female has also a greater quantity of milk, and her offspring is more than abundantly supplied with nourishment after birth.

"To produce the most perfect-formed animal, abundant nourishment is necessary from the earliest period of its existence until its growth is complete.

"The power to prepare the greatest quantity of nourishment from a given quantity of food, depends principally upon the magnitude of the lungs, to which the organs of digestion are subservient.

"To obtain animals with large lungs, crossing is the most expeditious method, because well formed females may be selected from a variety of large size to be put to a well formed male of a variety that is rather smaller.

"Examples of the Good Effects of Crossing the Breeds.—The great improvement of the breed of horses in England arose from crossing with those diminutive stallions, Barbs and Arabians; and the introduction of Flanders mares in this country was the source of improvement in the breed of cart horses.

"Examples of the Bad Effects of Crossing the Breed.—When it became the fashion in London to drive large bay horses, the farmers in Yorkshire put their mares to much larger stallions than usual, and thus did infinite mischief to their breed, by producing a race of small-chested, long-legged, large-boned, worthless animals."—*Southern Planter.*

ALTERING COLTS.

The treatment of animals has arrested my attention from the time when as a boy, I have witnessed, in the lower part of this State and S. Carolina, the yearly collection of marsh tackies, calves, &c., for the purpose of marking, branding, cutting out the lampas, emasculating, docking, &c., and to this time I have hailed with pleasure any improvement, especially in the treatment of that noble animal, the horse. By degrees I have seen the barbarous practice of burning out the lampas and cutting out the hooks, give way, at least among the enlightened, to the more rational, and I think more curative practice of depletion and change of food.

And now, having witnessed, I am induced to describe to you an improvement in the emasculation of the horse, which strikes me as being well worthy of being generally known.

When I came to this neighborhood a few years ago, I was told of a man who performed the operation without tieing the horse in any way, and I am free to confess that I thought it was a mistake; but now, to me, seeing is believing, although it yet appears strange. Being at the house of a friend on Saturday last, I had an opportunity of seeing the performance under the following circumstances:

A three year old colt, with a simple bridle on, was backed into the corner of a worm rail fence, where he was held by a youth of sixteen, without any other restraint than the bridle and fence. The operator approached the animal with the same calm sang froid that an old bee-master handles a hive which he is about to rob of its honey; going to the right side, he laid hold of the bag with the left hand, and with the right laid open one testicle, and separated it in the usual way, and then did the same with the other, and so left them without any ligature; he then enlarged the opening in the envelop skin so that all the blood which came might freely fall off; a spoonful of lard and salt was then laid in to prevent an accumulation of coagulated blood on the parts, and he was then unbridled and turned loose. During the operation, there were no great efforts made by the horse to get away, and he was easily held in by the bridle; he appeared to incline towards the operator, as horses frequently do when they are tickled by the curry-comb; and once or twice he threw up the near hind leg as if to drive off a fly. There were no evidences of his suffering pain, such as groaning or the like. The man said he had operated on hundreds, and never lost one, or had been kicked but by one, and was successful with either old or young horses. A. S.

ANALYSIS OF INDIAN CORN.

In our paper of March 22d, says the American Farmer, we gave an analysis by Professor Dana, of Lowell, Mass., of Indian Corn, Ruta Baga and Potatoes, upon which, among other things we then remarked:

"This analysis presents one other curious fact—it is this—that while the corn gives over 88 per cent of the *fat-forming principles*, and the potato only a little over 24 per cent; that in the *flesh-forming principles*, the potato greatly exceeds the corn, the former yielding 2.07, whereas the latter only gives 1.26."

This discrepancy between the product of *fat* and of *flesh*, in a grain so rich in nutrition as that of corn, appeared to us at the time to be strange, and hence the remarks we then made: we are pleased to find by the following correction, that the result as set down by Dr. Dana, to the flesh-forming principles of corn was erroneous; but while we make this remark, we must be permitted to point to another discrepancy which appears between the fat forming principles as stated in his note of correction, and that given in his communication of February 28th. In that communication they were stated at 88.43, in the present at 77.09, being a difference of 11.34, just the one existing between the present result, as regards the quantum of flesh forming principles and that formerly ascribed to it. This makes the aggregate result quadrate, but does not account for the error in the *fat-forming principles*, as the Doctor is silent as to how it occurred.

To the Editor of the New England Farmer:

Dear Sir—I ask leave to correct a material error in the statement of the results of the analysis of Indian corn which I send you, and which you published in your paper of March 8, 1843.

1.26 should be 12.6. Deducting this number, the product of multiplying the nitrogen of corn by 6.20, from the water of vegetation and the salts, we have 77.09.

The corrections thus made, the results are—

Flesh-forming principles—gluten, albumen, &c.	12.50
Fat-forming principles—as gum, sugar, starch, woody fibre, Oil, &c.	77.09
Water	9.
Salts	1.31
	100.

With regard, your ob't serv't,

Sam. L. Dana.

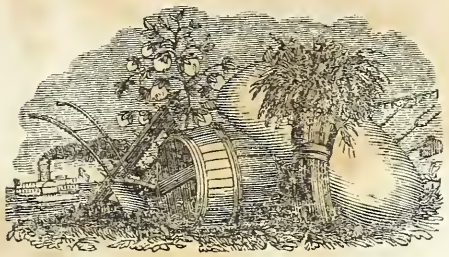
Lowell, June 10, 1843.

Incident.—The following singular incident, says the Central N. Y. Farmer, took place at Vernon Centre, in this county, on the premises of Gary Grant, Esq., and may be relied on as a matter of fact.

A heifer at the age of one year and ten days, brought forth a full grown and very good proportioned calf—the sire of which was not more than eleven months old at the time the calf came.

The above fact can be proved by the affidavit of respectable citizens, if it is doubted by any of our readers.

☞Nothing can be more touching than to behold a soft and tender female, who had been all meekness and dependence, and alive to every roughness, while treading the prosperous paths of life, suddenly rising in mental force to be the comforter and supporter of her husband under misfortune, abiding with unshrinking firmness the bitterest blasts of adversity.



WEDNESDAY, AUGUST 2, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

TO READERS AND CORRESPONDENTS.

PURE BERKSHIRES.—Either our correspondent, "J. M. G.," or we have misconceived "A LOVER OF GOOD HAM;" for had we supposed that he designed to convey the idea that there were no pure Berkshires in Georgia, we certainly should have corrected his error. Our understanding of his meaning was, that those hogs which had been brought from the West, by drovers, and sold in Georgia as Berkshires, are mixed blood, and as we entertain quite the same opinion, we of course did not dissent from his position.

In reply to the suggestion of "J. M. G.," that Col. BONNER furnish for the "*Southern Cultivator*," such facts as he may deem of value and interest to the farmer, relative to the value and capacities of the Berkshires, we have only to remark, that we should be pleased to give his views to our readers, and we doubt not they will be equally pleased to obtain the opinions of one who has so much experience on the subject in this climate, as our friend Col. BONNER, and we therefore hope he will favor us with a communication.

IMPROVED CULTURE OF COTTON.—The reader will find in this number, an interesting communication from Dr. CLOUD, of Alabama, on the subject of his improved method for the culture of cotton, to which we invite attention. In justice to ourself, we must explain to Dr. C. why it was that we only gave an extract from his letter to the Albany Cultivator. The extract appeared in the second number of our paper, which was issued before we obtained an exchange with the Albany Cultivator, hence we made the extract from another paper, which only contained that portion of Dr. C.'s plan that we gave. We do not however regret the circumstance, as it has been the means of affording us an opportunity to introduce the Doctor to our readers in an original communication—an acquaintance which we trust will be cordially cultivated by all parties, and which we doubt not will be highly interesting and instructive, and, we hope, mutually beneficial, for we flatter ourself that the Doctor will avail himself of every occasion his leisure may afford, to give us the results of his experiments for the benefit of our columns.

AGRICULTURAL PAPERS, &c.—We need not urge upon the reader's consideration the plain, practical suggestions of our correspondents, JOHN FARRAR and "A. O." They are told in a language which but too truly discloses their origin to be from plain, practical men, men whose views have been formed upon much experience and close observation, and they are, therefore, worthy the consideration of every planter. Especially would we invite attention to the acknowledgement of Mr. Farrar as to the value of agricultural papers. It is indeed strange that the great mass of planters, while they observe in every other branch of their business that sound maxim which teaches, "when you have failed by one system try another, and invoke to your aid the light and experience of others," it is strange, we repeat, that they should hesitate to adopt it in that most important of all other pursuits, agriculture. Nevertheless it is true—most lamentably true. Go where you will and you find men whose whole lives have been devoted to the positive destruction of the finest land on the globe, and while they are ready to profit by the experience and observation of others on any other subject pertaining to their interest, they reject most positively any suggestion about farming, improving lands, &c. &c., and scout the idea of "*book farming*," as the mere speculative theories of visionary men. We however rejoice to find this prejudice is fast passing away, and giving place to a more enlightened and philosophical view of the matter, and we are particularly rejoiced to have the testimony of such a practical man as JOHN FARRAR in support of agricultural papers.

THE IRISH FARMER.

The following sketch of an Irish Farmer and his farm is from the Irish sketch book, by Thackeray, which we hope may not pass unheeded by our Agricultural readers.

"Before setting out on our second day's journey we had time to accompany the well pleased owner of H——town, over some of his fields and out-premises. Nor can there be a pleasanter sight to owner or stranger. Mr. P——farms four hundred acres of land about his house; and employs on this estate no less than one hundred and ten persons. He says there is full work for every one of them, and to see the elaborate state of cultivation in which the land was, it is easy to see how such an agricultural regiment were employed. This estate is like a well ordered garden—we walked into a huge field of potatoes, and the landlord made us remark that there was not a single weed between the furrows; and the whole formed a vast flower-bed of a score of acres. Every bit of land up to the hedge-side was fertilized and full of produce; the space left for the plow having afterwards been gone over, and yielding its fullest proportion of 'fruit.' In a turnip field were a score or more of women and children, who were marching through the ridges, removing the young plants where two or three had grown together, and leaving only the most healthy. Every individual root in the field was thus the object of culture; and the owner said that this extreme cultivation answered the purpose, and that the employment of all these hands, (the women and children earn 6d and 8d a day all the year round,) which gained him some reputation as a philanthropist, brought him profit as a farmer too; for his crops were the best that land could produce. He has further the advantage of a large stock for manure, and does every thing for the land which art can do. Here we saw several experiments in manuring. An acre of turnips prepared with bone dust; another with 'Murray's composition,' whereof I do not pretend to know the ingredients; another with a new manure called guano. As far as turnips and a first year's crop went, the guano carried the day. The plants on the guano acre looked to be three weeks in advance of their neighbors, and extremely plentiful and healthy. I went to see his field two months after the above passage was written; the guano acre still kept the lead; the bone-dust ran the guano very hard; and the composition was clearly distanced.

"Behind the house is a fine village of corn and hay ricks, and a street of out-buildings, where all the work of the farm is prepared. Here were numerous people coming with pails of butter-milk, which the good natured landlord made over to them. A score of men or more were busied about the place, some at a grindstone, others at a forge; other fellows busied in the cart-house and stables, all of which were as neatly kept as in the best farm in England. A little further on was a flower-garden, a kitchen-garden, a hot-house just building, a kennel of fine pointers and setters—indeed a noble feature of country neatness, thrift, and plenty.

"We went into the cottages and gardens of several of Mr. P.'s laborers, which were all so neat, that I could not help fancying they were pet cottages erected under the landlord's own superintendence, and ornamented to his order. But he declared that it was not so; that the only benefit his laborers got from him was constant work, and a house-rent free; and that the neatness of the gardens and dwellings was of their own doing. By making them a present of the house, he said, he made them a present of the pigs and live stock, with which almost every Irish cotter pays his rent, so that each workman could have a piece of meat for his support; would that all laborers in the empire had as much! With regard to the neatness of the houses, the best way to insure this, he said, was for the master constantly to visit them, to awaken as much emulation as he could among the cottagers, so that each should make his place as good as his neighbor's—and to take them good-humoredly to task if they failed in the requisite care.

"And so this pleasant day's visit ended. A more practical person would have seen, no doubt, and understood much more than a mere citizen could whose pursuits have been very different from those noble and useful ones here spoken of. But a man has no call to be a judge of turnips and live stock, in order to admire such an establishment as this, and heartily to appreciate the excellence of it. There are some happy organization in the world which possess the great virtue of prosperity. It implies cheerfulness, simplicity, shrewdness, perseverance, honesty, good health. See how, before the good humored resolution of such characters, ill-luck gives way, and fortune assumes their own smiling complexion! Such men grow rich without driving a single hard bargain; their condition being to make others prosper along with themselves. Thus, his very charity, another informant tells me, is one of the causes of my host's good fortune. He might have three pounds a year from each of forty cottages, but instead prefers a hundred healthy workmen; or he might have a fourth of the number of workmen, and a farm yielding a produce proportionably less, but instead of saving the money of their wages, prefers a farm the produce of which as I have heard from a gentleman whom I take to be good authority, is unequalled elsewhere."

"THE GREAT AGRICULTURAL ERA COMING."—Under this head, the Long Island Star, after alluding to the labors of Liebig, Johnston and others, in connection with the application of the principles of chemistry to agriculture, says:

"A greater advance than heretofore has, we understand, been latterly made. Dr. Wm. Valentine, heretofore better known in other departments than that of a chemist, in which he has been well educated, and for which he has a natural aptitude, has been lately devoting his whole attention to agricultural chemistry. By

means of powerful apparatus, he has been analyzing soils with a view to applying the best means of fertilizing them, and has been learning the means of compounding by means of chemical agents, the best manures. He believes, (and other scientific men believe so likewise,) that he has acquired the art of enabling farmers to manure their land at one-tenth the ordinary expense of money and labor. His discovery has been patented, and he has recently been employed in laying vats on the farms of Wm. M. Weeks and others, at Glen Cove, and is calculating to extend his operations widely."

Since the above was in type, we have had an opportunity of conversing with Dr. Valentine, on the subject of his researches in agricultural chemistry. He explained to us the substance used, and the manner of making his artificial manure. That it will prove a powerful fertilizer, we do not doubt, and are glad to learn that its merits are being put to a practical test by several farmers on Long Island, the result of which will in due time be made public.

We have received a note from Dr. Valentine, setting forth the advantages to be derived from his discoveries, which shall have a place next month.—*Albany Cultivator.*

FIVE HUNDRED REASONS WHY LAND SHOULD BE IMPROVED.

More can be cultivated with the same hands, because tilled with less hard labor.

Briers and shrubs disappear, and grasses appear.

Cattle damage the land and grass less, because they do not have to tramp so great a space to fill themselves.

Less land required; less fencing.

Less trotting after cows and horses.

Less work at the smith's shop.

Fewer whips worn out.

Stronger teams

More manure, and less need for it.

A stimulus to action.

A protection against winter's frost and summer's heat.

A good example to children and neighbors.

Keeps off sheriffs and buzzards.

Stops emigration.

Produces money for books, and time for reading.

Surplus time and money for erecting buildgs.

Also school houses and churches.

Produces time to travel, to lecture on economy and preach the gospel.

Produces sociability and hospitality.

Makes a paradise of a barren, plenty out of poverty, a blessing out of a curse.

The barn is filled, the dairy is filled, the purse is filled, and the soul is filled with gratitude.

If the reader will reflect, he will discover that the number of good reasons why the farmer should improve his land, is almost innumerable.—*Albany Cultivator.*

Curious Result.—A friend has shown to us some scions, which he has just received from a gentleman on Grand Isle, Vt., which produce apples partly sweet and partly sour. This singular production was brought about in this manner. A bud was taken from an apple tree producing sour fruit, another from one producing sweet; the two buds were neatly cut into halves, and a half of each kind joined together, forming a bud which was inserted in the stock as usual.

We have often heard of this method of producing two distinct varieties of fruit in the same apple, but we have doubted it, and though our information appears to come now from a very respectable source, we are rather incredulous, though such a thing may be possible. It is easily tested and we hope the point will be settled. Our friend thinks to test by getting the two kinds of fruit from the scions sent him, but whatever fruit they may produce will prove nothing, unless there is proof of their origin. We have seen of natural fruit sweet and sour fruit in the same apple. We advise him to be thorough in his experiment and begin with the bud.—*Boston Cultivator.*

TO KILL WEEDS.

Is there any manure that will kill *weeds?* is a question not unfrequently put. Will nitrate of soda, or nitrate of ammonia, or guano, or urates? That such questions should be asked, proves one thing at least, that there is a general desire to know how to extirpate weeds. We wish we could add that they also indicate some acquaintance with the rudiments at least of vegetable physiology.

Weeds, like other plants, have each their peculiar constitution, prefer certain kinds of food, and perish on the application of others. We have seen a pound of nitrate of soda administered to a Seakale plant without visible effect; half an ounce would probably destroy a Rhododendron. Common stable manure is prejudicial to Coniferous plants, and in overdoses will kill them; an oak feeds greedily upon it. So it is with weeds. Excessive doses of salt will destroy all ordinary vegetation, weeds included, but promote the growth of asparagus in a most remarkable degree, thus proving itself to be a poison to one plant and a nutritious food to another. But salt cannot be used in large doses to extirpate weeds generally, because some, like the asparagus, may flourish under its action, and most crops will certainly be destroyed by it. Professor Henslow succeeded in destroying moss and weeds on gravel walks, by means of corrosive sublimate, green vitriol, and blue vitriol, especially the last. But corrosive sublimate destroys every living form of vegetation, as well as the weeds; and the two sorts of vitriol have no permanent action, encouraging the subsequent growth of many sorts of plants, and so promoting the vegetation of weeds rather than destroying it.

In practice, these chemical agents can only be employed for the destruction of weeds in certain special cases, such as the asparagus, which thrives under doses of salt, which kills most other plants; or as tobacco, which feeds greedily upon quantities of nitrate of soda, which would destroy any ordinary vegetation. In general, we must look to other means for ridding ourselves of troublesome weeds, and we shall find those means in *industry* and *common sense.* The two separate are good things, but they are better mixed together. The plain and obvious rule is to pull weeds up as fast as they appear, and while still in the state of seedlings. Then every plant that is removed is effectually destroyed, and leaves no young ones behind it.—Any boy, at half-a-crown a week, can be taught to distinguish them, and if the plan is persevered in, there will very soon be nothing for the boy to do. Strict attention must, however, be paid to their thorough extirpation when young; it will not do to pull up *almost* all, and to leave the remainder to seed; for in that case the labor has to be all gone over again.—*Gard. Chron.*

Salting and Preserving Butter.—We annex a receipt upon this subject, and will take this occasion to say, that we have no doubt it is a good one, though we should prefer one we have used and *know to be good.* The paragraph below states that butter, packed away as therein directed, will keep ten years. Upon this part of the subject we cannot speak from any knowledge of our own; but with regard to the time it will keep, put away agreeably to the receipt we shall give, we are enabled to speak advisedly, as our butter was potted in the month of June, and was as fresh and sweet when opened for use, in the month of December following, as when first made, having preserved all its richness of flavor.

We took six ounces of fine Liverpool blown salt, four ounces of saltpetre, and six ounces of loaf sugar, and after pulverizing the whole, so as to make a fine powder, we incorporated it with the butter, after the buttermilk had been thoroughly worked out, at the rate of one ounce to the pound, then packed it away in stone jars, the tops of which we covered, first with clean cloths, and then with bladders, so as to completely exclude the air. Thus treated when fresh and well made, we have no hesitation in saying, that butter would keep any desirable length of time, though we should be unwilling to risk the opinion that it would keep, as maintained in the receipt below, ten years.

To Salt Butter—Beat well up together in a marble mortar, half a pound of common salt, with four ounces of powdered loaf sugar; to every pound of newly made butter, (the milk being well drawn off by beating,) put an ounce of the mixed powder, incorporate it well; put the butter in pots for keeping. In about a month, not before, it will be fit for use, and it will continue for ten years as good as butter newly salted.—*Am. Farmer.*

☞ It is not by the exclusive cultivation of one faculty—however astonishing the result may thus be obtained—that a truly great mind can be reared; nor is it by the exclusive cultivation of the intellectual powers, while that of the moral feeling is neglected, that a truly great and good character can be developed.

AUGUSTA MARKET.

Tuesday p. m., August 2.

Cotton— Since our last report we have had a very quiet time in our cotton market until today, when sales were made of upwards of 400 bales, at prices fully ½ cent lower than at the highest prices since Christmas.

Money—Checks on the North cannot be had at any of our Banks at a less rate than ½ ₩ cent premium. Central Bank notes sell from 9 @ 10 ₩ cent discount, and State 6 ₩ cent Bonds at from 72 @ 74 cents.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

Advertisements pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞Post Masters are authorized to receive and forward money free of postage.

☞All communications must be post paid

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., AUGUST 16, 1843. No. 17.

IMPROVOMENT OF DOMESTIC STOCK.

Few things are of more importance to the agricultural interest of a country, than their domestic animals; and any decided improvement in the breeds, forms a solid addition to the productive wealth of a nation. For instance, any change in the character of our cattle, which, by adding to their weight, aptitude to feed, early maturity, &c. should give a gain of twenty per cent on their value, would increase the worth of this item alone about fifty millions of dollars.—That such an improvement might be made on the common stock of this country, there are few intelligent men that at the present time will doubt. Facts and experience are most conclusive on this point; and what is true of cattle, will also hold true of all other varieties of domestic animals.

But while most will readily admit the necessity and practicability of improvement, there are some differences of opinion among practical and well informed men as to the best methods of effecting it. Some contend that the only rational prospect of improvement is to be found in introducing foreign stock, and breeding from these, to the exclusion of all native animals.—There are others who maintain as strenuously that there is no necessity whatever for any introduction of foreign blood; that we have among ourselves, and in our own herds, all that is necessary to produce as perfect animals as any of the improved breeds of Europe. Others assert that the truth lies midway between these extreme opinions; that the true course is to import valuable animals, if they can be obtained, from abroad, and breed them to our most valuable and choice stock, taking care to select such as are the best adapted to produce any given result or quality. We shall examine these opinions in their order.

Careful and skillful breeding lies at the foundation of all improvement in stock, and this is mainly effected by judicious selections. Color, form, quality and disposition, are all under the control of the breeder. He can equalize and harmonize the whole, or he can develope one point at the expense of the others. It is rare indeed, perhaps never, that any single point is found in its highest degree of excellence, except at the expense of some other quality. Thus the taking on flesh rapidly, is incompatible, from the very nature of the case, with a copious secretion of milk; and the deepest and best milkers of the herd, may usually be set down as the most raw boned, not to say worst looking of the whole. The reason of this is obvious: the quantity of nutritive matter taken in the food is of necessity limited, and it is impossible for it to perform two offices, or rather be in two places at once. It cannot go to the formation of flesh and fat, and yet be secreted in the form of milk. The term *best*, then, as usually applied, may admit of a different meaning. The best animal for the grazier or butcher, is not necessarily the best for the dairyman; although there are few deep milkers that will not, when the secretion of milk is suspended, take on flesh rapidly—a fact which shows the incompatibility of the two.—The best animal, or the one which it should be the object of the breeder to produce, is the one that combines the most valuable qualities, and it is in this sense that the term should be always understood.

The number of those who insist that we are to look to England, and to the produce of importations from that country alone, for the improvement of our stock, is of course limited. There is something absurd in the idea of replacing the ten millions of our native cattle by imported ones, or their progeny, in any reasonable term of years. Besides, had we the means to make the importation, they have not the animals for us. Notwithstanding the attention paid to the breeding of animals in England, the number of the improved animals is still limited; and though cattle to meet any demand might be supplied, such as we should require, or ought to require, could not be had. Great changes in the character of the stock of any country, demand time. It has taken more than two hundred years since Gov. Winslow introduced the first three heifers and one bull into this country, to bring up our stock to its present numbers. This was in 1624; and time would enable us to fill our country with imported stock, were it necessary to wait for such a consummation. As the question, however, relates to present improvement, the idea of depending on importation wholly, must be discarded.

The second position, viz: that we have in our present native herds all the materials necessary for improvement, and that a recurrence to foreign improved breeds is unnecessary, is far more plausible, and has a much greater number of supporters, than the one we have just considered. It is argued, and truly, that all the improved breeds are made up breeds; that it is idle to seek for what may be called an original breed; that the varieties of domestic cattle are depending on climate, crosses, or perhaps in some instances on accidental circumstances; that the improved cattle of England have been bred almost within the memory of man, from old varieties already existing there; that what has been already done, may be done again, and that nothing but the same judgment in selecting animals to breed from, and the same skill and perseverance in following the laws of breeding to their results, is wanting, to produce as valuable stock from our native varieties, as has been produced from the native varieties of England. We have purposely stated this argument in its strongest form; because, while we admit the possibility of producing, in this country, improved breeds equal perhaps in value to those at present existing in Europe, we think it would be the height of folly to undertake the task, in preference to availing ourselves of the labors and skill of European breeders. To make ourselves understood, we will select the Short Horns or Durhams, as the breed best known, for the purpose of illustration.

We can trace the Short Horns, as a distinct breed, to its originators, Charles and Robert Collins, some fifty years since. Others, as Berry and Coates, co-operated most effectually in forwarding the improvement commenced by them; and within the last twenty years, the number of breeders of this stock has multiplied in every part of England. It cannot be denied that more skill has been exhibited, a greater acquaintance with the true principles of the improvement of stock acquired, and the real points that constitute the value of animals more fully developed in this case, than in any previous instance. Scarcely a variety of domestic cattle can be found, from which animals may not be selected, with one or more points as faultless, and as well developed, as in the improved stock; but in most cases, these valuable points must be considered as accidental, as experience proves there is no certainty of there being continued in their offspring. The science of breeding consists in uniting in one animal as many of these valuable properties as possible, and rendering them constitutional and permanent, so that they may descend to their progeny, or so that the danger of their loss may be avoided. This is what has been done in the case of the Short Horns. That their excellencies are permanent, and fixed in the breed, is proved by their invariably imparting more or less of them to any variety with which they are crossed; that the blemishes and faults occasionally to be found in them, are to be considered as accidental, and not inherent in the breed, is proved by the fact that these defects are rarely propagated or reproduced in their progeny. It has taken at least fifty years to bring up the Short Horns to this point of excellence; and there is no probability whatever that any modern skill or knowledge could materially shorten this period in engrafting these valuable qualities upon the native stock of this country, by simple selection and breeding from our varieties alone. We must, then, to raise up an American breed from native stock only, combining as many valuable qualities as the Short Horns at present possess, employ some fifty years, with much labor and money, and then find ourselves at precisely the point of improvement where the English breeders now are. We think, then, that the advocates of an exclusive American breed, or one produced from our native varieties, without reference to foreign stock, are guilty of as great an absurdity as those who would rely on imported stock only, to replace with an improved stock our native herds.

The third course for improvement is that of those who believe that the best way is, to obtain the best and highest bred animals from abroad, when such can be procured, and breed them to our best and choicest native stock, having reference, in our selection of animals, to those points we consider most desirable in stock, or in which, perhaps, the imported are the most deficient. And this is the method to which we give a decided preference, and to which, it is believed, we must resort and adhere, before any essential change in the character of our stock, generally, will be effected.

There are some who seem to suppose that we are to regard the high bred imported animals as perfect, and incapable, by any skill of breeding, of further improvement. No breeder, however, who has any knowledge of his profession, will view the matter in that light. He sees in the Short Horns, for instance, animals very superior to the common stock of the country; animals that combine a far greater number of valuable points, and are of consequence a decided improvement upon any native breed; but he is far from looking on them or any other breed of cattle as perfect, or incapable of further improvement. On the contrary, he sees in these improved breeds, and these fine imported animals, the basis of still greater improvements; he sees in them, what the labor of the most skillful and careful in England have taken fifty years to accomplish; and instead of going back to the point from which they started, he intends to make the highest vantage ground they have reached his

starting point in the career of further progress and improvement.

In breeding from foreign improved stock, it is necessary the American farmer or breeder should pay particular attention to the purity of blood, and the predominating qualities of the animal. The principal value of any improvement in animals, consists in its permanency; indeed, this quality is one of the main things that marks the difference between the high bred imported animal and *some few* of our native stock. If the improvement is not permanent; if the valuable qualities have not become fixed and constitutional, there is no security that they will be imparted to the progeny, or that the high raised hopes of the breeder may not end in bitter disappointment. It is in determining this question of blood, that the pedigree becomes important; and a reference to the Herd Book will inform the breeder whether he may depend upon stock possessing the qualities of their parents, or leave it to be determined by the event whether that stock shall possess most of the qualities of the Short Horn or the scrub. In regard to the qualities of the imported animals from which we expect improvement to our herds, it appears to us that there are two points that have been sometimes overlooked in making our selections. We have not paid attention enough to their milking properties, or their ability and aptitude to labor. The old Short Horns were the best milking breed in England—a reputation which, as a whole, certainly does not belong to the improved breeds. That there are some superior milkers among them, is notorious; and that milking deep might be made one of the peculiar characteristics of the breed, no well informed breeder doubts. We very much question, however, whether there is at this time in Europe or in the United States, a herd of *any* improved stock, Short Horns, Herefords or Devons, from which twenty five cows can be setected, that would produce as much butter and cheese as the twenty five native cows mentioned at page 79 of the May Cultivator, or that from the twelve native cows mentioned at page 85 of the same number.* The reason is a plain one; other qualities than deep milking have been principally regarded by their breeders; beef, and not milk, has been the great object. That deep milking can easily be bred into them, no one questions; and this we believe is one of the points that calls for immediate attention. Another point that has not been sufficiently attended to, is aptitude to labor. In this country, very few instances can be found in which high bred animals have been put to the test of labor; but in England, Short Horn bullocks have been subjected to the yoke, and, unless we are misinformed, were found in this respect inferior to the Devons or the Herefords. Indeed, the forms of the animals themselves, indicative of diminished activity and power of locomotion, would lead the observer to expect such a result; and by some it may be considered doubtful whether the aptitude to labor can be engrafted on this stock, unless at the expense of other more important and valuable qualities.

A question, most important to the agricultural interests of the country, is not unfrequently asked, and it is desirable it should be correctly answered; that question is, how can the desired improvements be most certainly and expeditiously made? On this point we are fortunately not left to theory alone; but we have the result of many experiments, which would seem to be decisive of the matter. In all crosses from a high bred or made up stock, with inferior breeds, there is a constant and powerful tendency to deterioration. Habit is hardly equal to a contest with nature; implanted qualities, unless carefully guarded, are apt to disappear before the powerful tendencies of natural and constitutional ones; and it is to prevent this degeneracy, to retain all the old qualities that are valuable, and add new ones that are desirable, that requires all the skill and caution of the breeder. Man himself, studied physiologically, has furnished some of the most useful lessons which can be offered for the guidance of the modern breeders of animals.

Our opinion as to the true course to be followed, and the one which we doubt not will be generally adopted, is, for the breeder to select a full bred bull of the kind preferred, possessing those qualities most desirable, o indicating that they are inherent in the breed. Much is depending on the proper selection of the male, for it is he that stamps most indelibly his character on the progeny. Ascertain whether the animals from which he is descended, the particular family, we mean, are noted for any particular quality, and what that may be. In the same breed, and of equal purity of blood, animals may be found in which the predominating quality differs essentially. Aptitude to fatten, deep milking, excellence in the yoke, kind handling, &c. &c. may not be prominent in all animals of a breed; and it is for the breeder to select with reference to the qualities, whether of form or color, most desirable. Having secured bulls of undeniable excellence, let the breeder next select from his native stock the best cows he possesses, or that can be procured—those in which the qualities of easy feeding, deep milking and kind dispositions appear to be the most strongly marked and fixed, and breed from such cows only, if he hopes to effect a permanent improvement in his stock. We have never known an instance in which such a cross did not at once mark and change the character of a stock for the better. The cattle shows and fairs of our country prove that these half bloods are far superior to the native stock, in every case where ordinary attention has been paid to selection in breeding, and that in many instances they have approximated in form and value to the pure blooded progenitor. In this *first cross* we have rarely known the farmer or breeder to be disappointed; it is in the next and succeeding steps in the progress, from which disappointment has arisen, and this has been occasioned by causes perfectly easy to explain. How often have we heard it said, "our first calves were almost equal to the imported bull, but now they are no better than old fashioned stock." And this was true; for they were nothing but the old stock. Let it be remembered that breeding from crosses, without recurrence to pure blood always degenerates; but where the first cross or half blood is bred to a full blood, a half blood heifer to a pure blood bull, for instance, improvement is sure to follow. The course pursued by many, perhaps most of our farmers is this. A native cow is bred to a pure short horn, and the progeny is a fine bull calf. This calf, a half blood, is used for a bull with his herd of native cows, and the farmer is surprised to find such a falling off in the qualities of his calves from that of their sire. Now the true course would be, if the progeny in the first instance was a bull calf, to fit him for the yoke or the shambles; if a heifer, to breed her to a pure blood bull, and a good calf might be considered certain. By this recurrence to pure blood, the stock will be constantly rising; by breeding from crosses without such recurrence, it will be as certainly sinking.—By proceeding in the way here pointed out, using full blood bulls and the best native cows, our stock as a whole would be rapidly improving, and the way prepared for an advance on any of the present breeds.

But it may be doubted by some, whether any improvement on the best of the present high bred cattle, is possible, and the idea of it be scouted as an absurdity. "What," it may be said, "talk of improving a breed by crossing them with those still lower in the scale?" We answer yes, and hope to show there is nothing chimerical in the plan. For illustration, we will again recur to the Short Horns, as unquestionably at the head of the improved breeds.—Breeders have enumerated a great number of points as going to make a perfect animal; to make one absolutely perfect, we will suppose that thirty enumerated qualifications are requisite; that the Short Horns, as approaching the nearest to this standard, possess twenty of the desired qualities; and the other varieties or breeds in a descending ratio down to our native stock, which may be put as possessing but five of these requisites. The question is, can an animal possessing twenty good points, be improved by one possessing only 10 or 5? We answer yes, if the one possessing 20 is deficient of any of the points possessed by the lowest, or by 5. 20 may be deficient in hardihood or the power of enduring our seasons; in milking properties; adaptation to labor; quality of flesh; or some other point or points, possessed in a remarkable degree by 5; and this deficiency remedied by a skilful cross with 5, which shall engraft and fix the valuable point on 20, would make it 21, or furnish a decided advance towards animal perfection.

The opinions we have advanced in this paper, are not to be considered as mere theory alone; experiment has in a great degree demonstrated their correctness. At our cattle shows, crosses of the improved breeds with our native cattle have been exhibited, which have placed beyond a doubt the possibility of rapidly improving our stock in this way, and by their superior qualities furnishing every incentive to the undertaking. But there must be no breeding downwards; every cross must be upwards both in blood and in desired qualities. We do not say that any animals have yet been produced equal to the finest of the improved breeds, but we believe some might be pointed out that would not suffer materially in a comparison with a great majority of our imported animals, for all the ordinary purposes of the farmer.

Believing as we do, that it is to skilful crossing of the improved pure stocks with our best native animals we are to look for the earliest as well as the permanent improvement of our herds, and the building up of an American breed worthy of the name, the importance of introducing and preserving animals which shall serve as the basis of this improvement, forces itself upon us at once. It is to the pure blood stock already among us, or which may be introduced, that we must mainly look; and every precaution should be used by the breeders of such stock, and every effort used not only to keep them pure, but to provide for their further advance by skilful breeding, and by the infusion of new blood occasionally, to prevent the enfeebling and degenerating effects of too close breeding. The breeders of improved stock can scarcely attach too much importance to pedidree, as in that alone have they proof of the endurance of the valuable qualities of the animals they breed; and the confidence of the public once shaken on that point, or any deception practiced, will be most unfortunate, as seriously tending to check the improvement of domestic stock. Men who do not look at the subject in all its bearings, are sometimes heard to complain of the prices paid for imported or improved animals, and denounce all efforts at improvement as speculation or mere money making.—We, on the contrary, view the improvement of our domestic stock of all kinds, as an affair of national importance, and think the public spirited individuals engaged in the business are richly deserving the approval and the thanks of the agricultural public. If they are well paid for their labors in the cause of improvement, we shall rejoice at it most sincerely; but we have yet to learn that any American breeder has found his purse grow inconveniently heavy, in consequence of his cattle sales. The men who add as efficiently to the national wealth as they do, are, to say the least, entitled to their share.

Albany Cultivator.

*In the dairy of 25 cows the product per cow was 561 lbs. of butter and cheese; and of the dairy of 12 cows the product per head was 533½ lbs. In both cases the cows had pasture and hay only.

INCREASING THE MILK OF COWS.—Gentle treatment and rapid and close milking, says the American Agriculturist, will tend to the greatest development of the milk in cows, and the contrary practices will have the effect of materially reducing the quantity.

THE MILK CELLARS.

A correspondent of the Farmer's Cabinet gives some important ideas on the advantages of good cellars for making butter. He considers cellars properly constructed, altogether preferable to spring houses. His remarks are founded on good sense and sound philosophy. Mr. Miller, the writer, lives in the vicinity of Philadelphia market, which shows as much perfect butter perhaps as any other market in the Union. His ideas are the result of the practice which has prevailed in that vicinity until it has become a distinct species, called Cellar Butter, and always commands the highest price. All dairymen and farmers would do well to construct cellars in conformity to the plan given by Mr. Miller, who says,

THE MILK CELLAR.

It is a curious fact, but by no means unaccountable, that in many parts of the country the milk *cellar* is superceding the *spring house*—an appendage that has always been considered indispensable for the production of good butter, be the other qualifications of a farm and its appurtenances what they might. While on a visit to Wilmington, Delaware, I had occasion to remark the excellence of the butter at my friend's table, when he replied he always selected the best cellar butter at market, for the use of his family, giving it as his firm conviction, that butter made in a cellar was far preferable to that made in a spring house, its great recommendation being, in keeping sweet and good much longer, and retaining its fine flavor and color to the last, which spring house butter would not do. And he observed, it is customary to account for the greater price which some dairymen obtain for their butter in the market, by saying it is *cellar butter;* instancing the fact, in the high character of that made by Mr. Bryan Jackson, near Newcastle, who never fails to obtain the top price of the market for butter of the finest quality; he having a cellar that might be taken as a pattern for all that part of the country. Of course, it is readily admitted that much depends on the mode that is adopted in the management of the dairy, commencing with the breed and feed of the cows, and ending with the manipulations of the butter; but the idea is gaining ground, that the best butter is to be made in a cellar, all other circumstances being equal; a remarkable revolution in public opinion truly.

On reconnoitering amongst my friends, I found that several of them had substituted the cellar for the spring house; and I do not know one who is not satisfied with the arrangement, except it be where the cellar is dug in a damp soil, or has been most injudiciously opened to the well, the evaporation from which fills the room with constant moisture, which may be found adhering to the walls, the ceiling and the wood-work, the shelves, and particularly the inside of the door, causing a damp and clammy feel, and a nauseous, mouldy smell, which the butter imbibes, to its lasting injury: indeed no good butter can be made in such places. But another revolution is taking place, even among the advocates for the cellar: it is no longer thought necessary to dig the cellar very deep, or to arch it over with stone or brick, with an air passage through it for ventilation—a *vault* as it is more properly then termed; it is found sufficient, if the cellar be sunk a few feet below the surface of the earth, with a wide and shallow window on each side, the bottom of it level with the ground outside; well protected with a wire guard to keep out vermin, large flies, &c., and provided with a close glazed sash, which can be opened and closed at pleasure, by lifting it up to the *ceiling*, which ought to be no higher than the top of the windows, so that the air of the cellar can be ventilated by opening the windows of the opposite sides, according to the way the wind sets at the time, shutting them quickly when necessery; for in cold, windy or damp weather, the sooner the windows are again closed the better. Indeed, to the management of the cellar in this particular, much of the success of dairying is to be attributed; cold and damp air being unfriendly to the secretion of cream, and its proper and entire separation from the milk. Hence, therefore, it is a bad practice to set the pans on the brick floor of the cellar; they ought always to be placed around on shelves, about three feet in height, and these, after being well washed with hot water, should be wiped quite dry, that no mouldy evaporation might take place to spoil the butter. The air near the floor of a dairy is always impure, being loaded with acid vapors and putrid exhalations, the density of which confines it to the lowest part of the room; hence it is, that the doors of some dairies are made with lattice work, that the air near the floor, as well as that near the ceiling, might be ventilated at the same time; these lattices being furnished with sliding pannels to be kept closed in bad weather. The milk cellar ought always to have a northern aspect, and be well shaded by trees, not growing too near the windows, so as to impede a dry current of air, or to create a moist atmosphere; this consideration being of more importance than would readily be imagined.

Cellars thus constructed and carefully attended, will, no doubt, supersede the use of spring houses generally, before many years have passed away, by which the business of the dairy will be rendered more agreeable, less laborious, and far less inimical to the health of those, particularly the females, whose occupation it is to attend to its never ceasing duties.

T. MILLER.

Delaware, June 13th, 1843.

ACID IN WOOD—ITS EFFECTS ON SALT AND BUTTER.—It has been frequently remarked by those who are in the habit of packing butter, that it kept best put down in stone; the next best is oak or white ash firkins, the wood of which had been boiled for several hours previous to working; and that butter packed in firkins of unprepared wood frequently acquire a strong and disagreeable flavor, which seriously injures it. The reason of this has not been generally understood. Mr. Moir of Scotland, has been instituting a series of experiments on the subject, which appear to have thrown some light on the matter. He found that most kinds of wood contained considerable quantities of pyrolignic acid, which decomposes the salt with which it comes in contact. The Linden or Basswood was the only wood he found entirely free, but the other kinds he experimented upon, were easily freed from the acid by boiling three or four hours, well pressed under water. It is evident that firkins made of staves prepared in this way, would be decidedly improved, and as the preservation of butter in a sweet and pure state is an important matter to the dairy man, we think much would be gained by a proper attention to vessels in which it is packed.—*Sat. Courier.*

CONVENTION OF BREEDERS.

(CIRCULAR.)

ALBANY, June, 1843.

The State Agricultural Society of New York, desirous that some fixed principles should be established as the basis of excellence in the various descriptions of farm stock, (without reference to their *relative* merits as breeds,) have appointed the undersigned a committee with instructions to call the particular attention of breeders throughout the States, to the importance of the subject, and to make the necessary arrangements for a Convention to be held at the Library Room of the American Institute, in the city of New York, during its 16th annual Fair, in the month of October next, the day to be hereafter noticed; at which breeders of stock and those interested in Agriculture, are respectfully urged to give their attendance, with a view to a full discussion of those forms, qualities and properties which most conduce to intrinsic value; and also that the distinctive characteristics of each separate breed may be as closely defined as possible.

The Society believe that the decision of such a meeting will offer to the agriculturist the best information that can, at present be elicited; and which they trust may be so satisfactory to the mind of every intelligent breeder, as to lead to greater uniformity of action and opinion, and *possibly* become a standard with them by which to judge and be judged, in all cases of competition.

With these views of the subject, the committee hope you may deem it of sufficient importance to be present at the proposed Convention, and lend to its discussions the aid of your experience and talents.

The committee will be obliged by any suggestions, in the interim, you may consider of sufficient importance to be communicated to them in relation to this subject.

FRANCIS ROTCH, C. N. BEMENT,
E. P. PRENTICE, GEORGE VAIL,
LEWIS F. ALLEN.

☞Editors of the several agricultural papers in the United States are requested to publish or notice the above.

COLIC IN THE HORSE.

To the Editors of teh Albany Cultivator:

In your number for May, I notice an article on "Colic in the Horse," and it gives me much pleasure to be able to concur with you most fully in regard to the severity and danger of the disease; and for the most part also in the treatment, which, so far as it goes, is in every respect unexceptionable; and I think it not improbable that when resorted to in proper season, will, as Mr. Stewart believes, succeed in eight cases out of nine.

The ninth horse, however, ought to be saved if possible, and I as freely believe that this last object may be attained in *every true* case of colic, as that the first eight will be saved by the remedies proposed. I cannot agree with you that the first object in the treatment is to arrest the fermentation, or that this is a primary cause of colic, believing it to be only one of the consequences. However this may be, I would rather say that the first object is to allay the pain—to relieve that excruciating agony which is, I apprehend, the very first morbid change which takes place in colic, and which being suspended, all other morbid phenomena subside of course, unless disorganization of the intestines has already taken place. This object can always be attained by the proper use of opium—exhibited either alone or in combination with the stimulants advised by Mr. Stewart. The last, however, I should think might be essential when there are evident symptoms of exhaustion and prostration of strength.

In cases of much severity, two ounces of a saturated tincture of opium, (laudanum,) may be given every half hour, till the pain is relieved, and if the symptoms are peculiarly distressing, three ounces may be given once in twenty minutes.

If the belly is distended and very hard, a moderate bleeding may be conjoined with this treatment with advantage.

I have known 8 ounces of laudanum administered in two hours, with perfect relief in a case of great severity, when all other remedies had failed of even mitigating the symptoms.

Very respectfully, H. WATSON.

East Windsor, 1843.

The following toast, given at Nashville on the Fourth of July, is an exception to the general character of the toasts reported this year:

By John Fitzsimmons. *Washington*—Providence left him childless, that the Nation might call him Father.

☞Burke once mentioned to Fox that he had written a tragedy. "Did you let Garrick see it?" inquired his friend. "No," replied Burke, "I indeed had the folly to write it, but the wit to keep it to myself."

INSTRUCTION IN AGRICULTURE.

The extract which we give below, says the Louisville Journal, from F. H. Burrows' report to the Legislature of Pennsylvania, has an important bearing upon agricultural instruction. It is a plan which contemplates permanent schools and professional teachers. These may be educated men, able to give instructions in the various scenes connected with agriculture and horticulture in a practical manner, using the ground they occupy for illustration and experiment:

TEACHERS' HOUSES AND LOTS.—There are as yet few teachers' houses provided by the districts. But the system will not be complete nor the profession of teaching permanent till they are possessed.

The teacher is now a wanderer. He engages for a month, a quarter or a half year in one neighborhood, and next season is perhaps found a hundred miles off, in pursuit of his precarious subsistence. * * * *

By this itinerant life, he either soon becomes disgusted with his profession and leaves it the first opportunity, or loses his hope and his energy; and with him sinks the respectability of the profession. There are, it is true, many and bright exceptions, but it is at the general rule and not the exception that we are to look.

In addition to the stability of increased usefulness which a permanent and comfortable residence for the teacher will produce, it will also be a great saving to the districts. A teacher provided with a comfortable house and garden for the whole year, will certainly demand less for his services than he who is obliged to board out or rent. Being comfortably placed for the year, he will be induced to open a private school, after the termination of free teaching, (in districts where the public schools can be sustained but part of the year,) and thus be found at his post when the district school re-opens for the next season, and will be enabled to teach for less than if he were obliged either to move his family every six months or be out of employment half his time.

The subject of teachers' houses is here introduced to bring it to the notice of directors, especially in new counties where land is cheap. They will find it to be very much to their future advantage, if they now, in providing school lots, procure them of sufficient size for a teacher's house and garden, in addition to the school house and play ground.

The following, from Beard's travels in Northern Europe, says the Journal, show that the plan which Mr. Burrows proposes has been tried, and is no longer to be considered an experiment If this succeeds in Denmark and Norway, where the greatest economy in education, as in everything else, is required, it certainly could be adopted with equal success here.—Could houses and grounds be furnished teachers, the great obstacle to making teaching a profession would be removed, and the interests of scientific agriculture and public instruction would be closely united. It is perfectly plain that, until this profession be established, educated men, those only who can give agricultural instruction, will not engage permanently in teaching. Concerning the schools of Dermark, Mr. Beard says:

"The stranger who journeys in this country cannot avoid being struck with the great number of schools which he sees as he passes from village to village. The parishes are required to pay the salaries of the teachers. This is done in a variety of ways. In the first place, almost every school has adjoining to it, or at least not far from it, the house of the teacher, together with a few acres of ground which belong to it, and of which the teacher has the occupancy as a part of his wages. In the next place he receives a certain quantity of grain and other productions from the parish, also as part of his salary. In the third place he receives some money, but in general not a very considerable sum; for the wages of teachers are low in this country where living is cheap, and where salaries of all kinds are not great. As a general thing they pursue the business for life; and certainly no men render more important services to the State than those of them who are capable and faithful."

Again, in reference to the schools in Norway, he says—

"The salaries of the rectors, as the schoolmasters are called, vary much, according to the different circumstances of the country. Usually each school district has a house for the teacher adjoining the school; and, in addition to his salary in money, pays him in kind or nature, as it is termed, a portion of the productions of the ground or other means of their wealth. In general the teachers are enabled, from their various incomes, to live with a good degree of comfort."

TO YOUNG MEN—FARMERS' SONS.

In addressing this class of readers, I wish to lay aside the dignity of the editor, and come among you as one of your own number. For I too am a young man, and a farmer's son; and *I know from experience* what disadvantages you labor under in the pursuit of knowledge, and what numereus discouragements you meet in your efforts for intellectual improvement. But I also know, that if you have the *will* you can succeed in making great attainments; and I know, too, that there is a great work for you to do, and great things will be expected of you.—Immense responsibilities rest upon you, as those who are about to assume the management of our much-abused farms—as those to whom the community must look for that reform in our practice of agriculture which is so imperiously demanded at the present time. It begins to be plainly seen that it will not do for you to follow in the beaten tracts of your fathers, and content yourselves with doing as they have done. They received their lands at low prices, fresh from the hand of God, abounding with fertility, and producing plentiful crops with little skill or labor; while the absence of western competition enabled them to obtain a ready market for all their surplus; and their simpler habits and fewer wants, rendered it less difficult for them to attain respectability and happiness in their profession. But how different is your situation! You obtain your lands at high prices, and many of them so impoverished by a long course of bad culture, that the staple productions are greatly diminished; or the fields are so filled with noxious weeds, that a double amount of labor is necessary to obtain even a scanty crop. While the competition from the vast West is so great and increasing, that prices must be very low.

It is affirmed by some, that the wheat crop of Western New York has diminished, in the average yield per acre, one quarter, or 25 per cent, in ten years! How long will it be, at this rate, before our great staple will not half pay for the labor required to produce it? Do you say this cannot be helped—that it is impossible to keep up the wheat-growing capabilities of our soil? No such thing. *It is possible*—yes, and easy too, not only to keep it up, but to increase it; if we will only accept the aid which science offers.—Look at what has been done in Great Britain. With soil not equal to ours by nature, and a less favorable climate, in districts where science has been combined with intelligent industry, the wheat crop has steadily increased in yield, at as rapid a rate as ours has decreased; so that forty to fifty bushels per acre are now frequently obtained, where at one time, with as much labor, the yield was only half that quantity.

But you will ask, "How are *we* to obtain this knowledge? We have only a plain school education, and are obliged to devote nearly all our time to labor. Scientific learning belongs to colleges, and those who are not obliged to work for a living." Here again is a great mistake, and one which the *Cannot* family are very apt to fall into. I unhesitatingly affirm, that there is scarcely a young man in Western New York, of ordinary intellect, who cannot, if he has the *desire*, make himself familiar with all the most important sciences connected with agriculture. Within a few years past, so many excellent and cheap books have been published, in which both theory and practice are explained so that all who read them can understand, that there is no longer any good excuse for remaining in ignorance. It is true there is one thing greatly needed in this country, which is not yet supplied; but, if young men will make their wishes known, it soon will be. We mean an Experimental School of Agriculture. To those who could devote a year or two to the subject, such an institution would be of more benefit than many years of reading. Let none delay, however, and let none repine because they are obliged to labor: to labor is noble—yea, is a blessing. Only make good use of the time you have, and of the powers God has given you, and you can rise above all difficulties, and will find the profession of agriculture afford you more true enjoyment than you now conceive possible.—*New Genesee Farmer.*

LIME A STIMULANT.—Admitting to the fullest extent, all that has been advanced by way of eulogium, in the use of lime as a fertilizer, a neutralizer and a sweetener, I have been accustomed to view it in another light, which has with me, the sanction of experience. I find it the strongest of all stimulants, rendering what was sluggish and inert quick and volatile, producing a vigor of growth in the plant often astonishing. And I have compared this result to the stimulating effects of ardent spirit upon the human frame, which is sure to bring out all the vigor that is in it, enabling it to perform prodigious labor, and sustain, for a while, the greatest bodily exertion. But, unfortunately, the parallel holds still further, for like it, the effects are but momentary, and when the unnatural stimulus is expended, a lassitude is felt in exact proportion to the excitement that had been administered. An this is a law of nature which must be obeyed, before an equilibrium can again be brought about.

Now, reasoning from analogy, must not the same deleterious effects that are observable in the man addicted to the use of ardent spirit, follow a too copious use of lime in the soil?—And does not this consideration account for the fact, that in Devonshire, where far more lime is used than in any other part of England, the average produce of grain is much lower than on any other of their soils of very inferior natural quality? It would therefore appear, by parity of reasoning, that lime should be followed by something for it to feed on, namely, barn yard or other substantial manures, that add staple to the soil, and counteract the too stimulating effects of an overdose of lime; an article better calculated to produce grass than grain. A man accustomed to take alcohol on an empty stomach, soon finds himself in a woeful state of exhaustion, quite unable to sustain even a moderate share of exertion for any considerable length of time—would it be allowable to apply the same mode of reasoning to the system of liming to excess?

It is asked, with much deference, what would be the results of an extra pulverization and thorough working of the soil, by fallowing on proper occasions? Would the system operate precisely in the way in which lime is said to act, in sweetening the soil, neutralizing its acidity, and adding to its fertility, by repeatedly exposing it to the action of the air and rain, and the influence of the sun—effects, which it is averred, would be found of the most lasting benefit, and causing an evenness and regularity in the crop, so necessary to its full developement.

Farmers' Cabinet.

WHEAT DOES TURN TO CHESS.

To the Editor of the Prairie Farmer—

I saw in your third number, a communication saying that wheat does not turn to chess.—I must disagree with the writer of the article. Some five years since I saw by the side of the fence a bunch of wheat and chess growing together. I had the curiosity to pull it up, and after washing the roots clean I examined the root, and found only one main root, from which shot up five stalks, two bearing wheat heads upon them and the other three chess. This was exhibited to hundreds, who all gave in that wheat and chess spring from the same root, or at least that wheat turned to chess. Where I found this it had the appearance of having been bitten off by something, at which place there seemed to be a large quantity of chess, while the other part of the wheat was clear from it. From this I am led to believe that where wheat has got so far advanced as to form the stalk and the stalk is then destroyed, it will grow up chess.

P. SWEAT.

Peoria, Il., March 17, 1842.

WHEAT AND CHESS.—As the question whether wheat becomes chess is a matter of vigorous debate, pro and con, we give the result of an experiment made by Newton Crawford, Esq., of Winnebago county, several years ago, and detailed to us by him. He had a piece of ground, on which no wheat had been grown, which he could flood at pleasure. He made three beds, which he sowed with perfectly clean wheat, selecting the seed by hand, one by one. One bed he let entirely alone after sowing; another he flooded with water, letting it off when he found it likely to draw out the wheat, and continued to do so all the spring and early part of summer. The third bed he fed down with some pet sheep, and continued to do so frequently, taking care to let them trample it down as much as possible. The result was, that the two beds whose growth he retarded by water and feeding, produced but little wheat, and some of it but half ripe: but the production of the three beds, as far as there was any production at all, was wheat, and wheat only—not a spire of chess appearing in the whole.

This experiment is only of a negative character, 'tis true: still, as those who believe wheat turns to chess allege that flooding and breaking the stalks are the principal agencies by which the change is effected, there is a pertinency in the experiment as far as it goes.—*Prairie Farm.*

CHARCOAL AS A FERTILIZER.—We have been astonished at the enormous increase of the wheat crop in France within the last eight or ten years, and have devoted some attention to the investigation of the subject. It appears that charcoal—an article that can be obtained here for a tithe of its cost in France—has been extensively used, and with marked effect, in fertilizing the wheat lands of that kingdom. A correspondent of the New Farmers' Journal, an English print, states that during a sojourn in one of the central departments of France, he learned that some of the most productive farms were originally very sterile; but that for a number of years their proprietors had given them a light dressing of charcoal, which had resulted in a large yield of wheat of an excellent quality. Since his return to England he has tried the experiment upon his own lands, with the same happy effect. The charcoal should be well pulverized and sown like lime, after a rain or in a still damp day. Even in England, the writer says, "the expense is a mere trifle, in comparison with the permanent improvement effected, which on grass is truly wonderful." He states one other very important result from its liberal use. "I am quite satisfied that by using charcoal in the way described, *rust in wheat will be entirely prevented*; for I have found in two adjoining fields, one of which was coaled, and the other manured with farm yard dung, the latter was greatly injured by rust, while that growing in the other was perfectly free from it.

Buffalo Com. Advertiser.

To the Editor of the American Farmer—

I should like you to give your reasons why you prefer that grasses should be mowed as soon as they are in *flower*. Our experience suggests that cutting should be delayed until it is so near ripe as not to scatter. Our grass is the "herds," or as it is called with you, the "red top."

Yours, very respectfully, H. A. L.

Pittsboro', N. C., July 5, 1842.

Reply by the Editor of the Farmer.—In reply to the inquiry of our correspondent, we have to state that our reasons are two-fold—*first*, that cattle relish the grass better, and *secondly*, that the soil continues longer in heart, inasmuch as prior to the formation of the seed a larger portion of the nutriment of the plant is derived from the *atmosphere*, whereas, after the commencement of the development of the seed, the major portion of the sustenance is abstracted from the soil, thus depriving it of its fertility without contributing to quantity in the weight of the hay. It is fair, however, to state that grass cut after the seed is ripe, or partially so, is more nutritious than that which is cut when just in flower.

SPURREY FOR SANDY SOILS.

This is a plant which is cultivated to a great extent in Denmark and Flanders, on the poorest sands. It is considered there as the most profitable crop that can be grown on very thin soil. Von Voght says: "It is better than red or white clover; the cows give more and better milk when fed on it, and it improves the land in an extraordinary degree. If the land is to lie several years in pasture, white clover must be sown with it. When sown in the middle of April, it is ripe for pasture by the end of May. If eaten off in June, the land is turned flat and another crop is sown, which affords fine pasture in August and September. This operation is equivalent to a dressing of ten loads of manure per acre. The blessing of spurrey, *the clover of sandy lands*, is incredible when rightly employed."

It is used as hay as well as for pasture, and is eaten greedily by sheep. The reeds are rich and highly nutritious for all kinds of stock, and afford, when expressed, a valuable oil. We think our poorest sandy soils, such as are to be found on our Atlantic coast, which are not rich enough for clover, would be admirably adapted to this crop, and its introduction might be the means of affording a profitable rotation with rye, and eventually produce, with judicious management, an entire renovation of extensive tracts, of what is now almost entirely waste land. Schwartz, who is esteemed high authority in Germany, says, "without spurrey, the Campine (Kempenlane, a district in Dutch Brabant,) *the best cultivated soil in the world*, would still have been a desert. It requires no manure for itself, and even when mown, by the residue it leaves, it gives back more than it takes from the soil; and except for seed, it requires no preparation, and it will grow where no other crop, except rye, will live." Will some of our enterprising and intelligent farmers, having land adapted to this crop, give the experiment a thorough trial? R. L. A.

American Agriculturist

EFFECTS OF SOAPSUDS ON CABBAGES.—I believe it will be a thankless piece of service for one gardener to teach another how to grow cabbages and cauliflowers, yet as these crops of vegetables have failed this season in various parts of the country, the following notice may perhaps be of use to our cottage readers.—Wherever soapsuds have been used plentifully, cabbages and cauliflowers have grown luxuriantly. I have made several inquiries of others who have used them, and in no one instance have I heard of a failure where soapsuds have been applied. I intend to try them over brocoli, to see if they will prevent them from clubbing. Others may do so likewise and make known the results. Whether the alkali in the water has prevented the enemy from destroying the roots, and given the roots more vigor to resist the attack, I do not know; but one thing is certain—where such matter has been applied, it has produced the most beneficial results. I think cottagers may take a lesson from this, and save that which would nourish their languishing crop, for it is a pity to see a pool of filthy water polluting the neighborhood with its stench, while within a few yards of it, the vegetables of a garden are dying of starvation.—*Gardner's Chron.*

THE FARM.

The farm is the home and the abiding place of the husbandman and his family. It is there all their social and domestic comforts and happiness are sought and enjoyed. It is there they unite their sympaties, their property and individual efforts, in common stock. By the proper application of their mental and physical powers, they can convert the farm into an earthly paradise. They can impart to it a neatness, fertility and rural beauty, which will endear it to them, above every other spot on the face of the earth, that they may emphatically call it "Home, sweet Home."

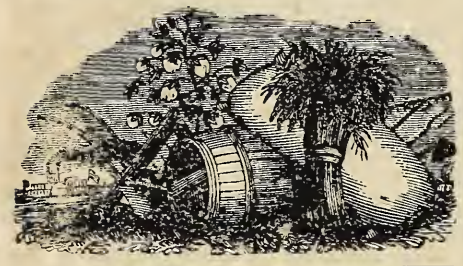
The farm which furnishes full scope for all the mental and physical energies of the owner for a long time, will in some measure become the true index of his moral, intellectual and physical character; the living epistle of his life and labors, and in no department of the establishment do these traits of character appear so conspicuous and beautiful, as in that necessary appendage, the well cultivated garden.

Horticulture is the perfection and refinement of agriculture in miniature. It was the first employment which the Creator assigned to man, while in a state of innocence. With a delightful climate, a rich and fertile soil, Eden no doubt abounded in fruits, vegetables and flowers, "inexhaustible in variety, beautiful in form, splendid in color," delicious to the taste, charming to the sight, and grateful to the smell—exciting the most pleasureable emotions in all the senses. For "there out of the ground the Lord God made to grow every tree that is pleasant to the sight, and good for food." All these delicate and exquisite pieces of workmanship were planted by God to adorn and beautify the garden assigned to Adam and Eve for a home, during their long sojourn on the earth; and were expressly calculated to produce in their minds the most exalted and sublime conceptions of the wisdom and goodness of their Creator. The structure, habits, character and usefulness of the vegetable world, the manner and means by which this wonderful combination of beauty and elegance are produced, afforded them a delightful subject for contemplation and study.—The simple process of fluid circulation, which by the influence of heat, light and moisture, gives all the variety of form, and size, and tint, and splendid dyes, that beautify and adorn the vegetable world.

> "Such beauty and beneficence combined,
> Shade unperceived, so softening into shade,
> And all so forming an harmonious whole,
> That as they still succeed, they ravish still."

The very name EDEN signifies pleasure, and no doubt God selected it as the most delightful plat for a garden, for a home! on the face of the earth; so that Adam first opened his eyes upon a most exquisite assemblage of beauty, in the variety of vegetables, fruits and flowers, in which he found himself enveloped. It was his home! A scene too fascinating, too tempting for frail humanity to withstand! It was to the garden, the sweet and sacred retirement of a rich and fertile garden, that the Savior of the world frequently resorted with his disciples, for solemn and devout meditations, and religious conversation and exercises. It was the only place in the immediate vicinity of Jerusalem, of which we know, that we find him familiarly frequenting as his home. It was there he went to contemplate the solemn hour of his sacrifice and suffering. It was there we find him giving utterance to his agonizing prayer in view of his approaching crucifixion. It was a spot which he had probably contributed to improve and

beautify by the labors of his own divine hands. —But independent of these hallowed associations, the garden and gardening possess many attractions for physical and intellectual man. It tends to promote bodily health, cheerfulness of mind, good morals, chastened affections and refined taste, so that a farmer's house without a well cultivated garden, seems destitute of the most delightful appendage of the Christian's Home; for among all the employments and enjoyments of the Farm, none creates and strengthens domestic attachments so much as this. —*Conn. Farmer's Gazette.*



WEDNESDAY, AUGUST 16, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

☞The prevalence of the INFLUENZA among the hands in our office, must excuse us to our patrons for the delay in issuing this number of the "Cultivator."

ERRATA.—In the communication of Dr. CLOUD, in the "Southern Cultivator" of the 2d inst., two errors occurred which we deem it necessary to correct, viz:—In the top line of the 3d column, after the word "*accomplished*" the point should be a comma or dash, instead of a period. In the 5th line from the bottom in the postscript, read "*attained*" for "*attained.*"

A FINE BERKSHIRE PIG.

The subjoined letter from our friend Colonel JOHN. BONNER, is sufficiently explicit, and we merely give it a place to make a suitable acknowledgement for his courtesy, and to thank him most sincerely for the pig, which it describes most graphically. He reached his destination safely, and, we beg leave to assure our friend, answers our highest expectations of the produce of "ONTARIO" and "LADY HUTTLESON," both of whom we saw on their passage through this city. And as a mark of respect to our friend, as well as our anxiety to possess a superior Berkshire from stock so approved, every possible attention shall be bestowed on him, to make him all that his distinguished parentage will justify a hope for.

WHITE PLAINS, July 29, 1843.

GENTLEMEN—I have this day caged and sent you a fine Berkshire pig. He is now two months old, and I think will make a splendid hog, with good treatment. He has several white spots over and about his body, all four feet are white, a small white tip on the end of the tail.—His face is entirely white, with the exception of a small black spot about the size of a cent piece in the forehead, or a little below it. His ears are very erect, and the inside of them show some white, more particularly the left one.

I have been thus particular in describing him, least he might escape on the way. He is out of my imported sow "Lady Huttleson," and by imported "Ontario"—both of which you saw as they passed through your city. He is not large for his age, attributable, no doubt, to many causes:—1st. The voyage to sea of his dam so shortly before pigging; 2d. His dam produced fourteen pigs at that litter; 3d. She did not stand our climate well; and 4th. She gave but little suck for so many pigs. He is, however, a *Berkshire*, every *inch* of him, the opinion of "A Lover of Good Ham" to the contrary notwithstanding.

I have no doubt but if he is well cared for, and not permitted to go to sows at too early an age, that he will fully equal his sire in every respect.

My stock are now doing well, and I am selling all the pigs I can raise. "Ontario" has improved greatly since his arrival, and, in my feeble estimation, is decidedly the finest formed hog I ever saw.

Hoping that the pig presented you may arrive safe, and ultimately exceed your expectations, is my greatest wish, and with my hearty thanks for your many favors, and a hope that your noble efforts to improve the agriculture of our country may meet its due reward, I remain, as ever, very truly yours, JOHN BONNER.

BOMMER'S MANURE.

In reply to several gentlemen making enquiries as to the source whence information may be obtained as to this method of making manure, we refer them to the advertisement of Messrs. ABBETT & Co. of Baltimore, which we have transferred to our columns. We know of no other agency in the Southern States, and presume there is not another, as we have not seen a notice of any. We would, however, most respectfully suggest to Messrs. A. & Co. the propriety of establishing one in Georgia, for the accommodation of those of our planters who desire to avail themselves of its advantages.—Some of our correspondents have propounded to us many enquiries with regard to the method, as to its cost, whether a man who is not a chemist can use it, and what substances it will convert into manure, &c. &c., none of which can we answer as definitely as we should desire. We have no doubt however that the materials employed are cheap, and can be used by any man who can comprehend the plainest prescription, and we take it for granted it will convert all substances into manure which are usually thus appropriated—even tan bark. In conclusion, we must remark to our correspondents, that they can form as definite conclusions as to its merits as we can, if they have carefully read all the extracts we have copied into the "Southern Cultivator," for we have regarded it a subject of vital importance, and have given them whatever information we could obtain from our exchange papers.

We subjoin a letter from Messrs. Abbett & Co., in reply to the remarks of our correspondent "H.," in which he alludes to Bommer's method. Messrs. A. & Co. will perceive on reference to the communication of "H.," that they have fallen into error as to his data—probably they have been led into it by the typographical error of the paper which copied the article from the "Southern Cultivator." "H." asserted that it would require "1500 to 1800 gallons of water to every 1000 lbs. of straw," and *not* 100 *lbs. of straw* as quoted by Messrs. A. & Co. This fact makes them approximate nearer in their views, but they are evidently yet far apart as to the quantity of water necessary to be used in this process.

BALTIMORE, August 8, 1843.

To the Editor of the Southern Cultivator—

Sir—As the proprietors of the patent right for the "Bommer Manure Method," an extract has been shown to us, copied from your paper, in which a correspondent of yours, signing himself "H.," states that "the method requires from 1500 to 1800 gallons of water to every 1000 lbs. of straw."

As your correspondent evidently makes a "right," we think that it will be easy to convince him that in this respect he has fallen into error.

In the first place he will acknowledge that the great bulk of water which is used is retained in the heap; that great care is taken to prevent loss either by filtration or evaporation; that if it is not retained in the form of water, the elements into which it is decomposed must still remain there in some other form, and whatever form these elements may assume, their aggregate weight will detect the amount of water which the heap has absorbed and decomposed.

Now we have the testimony of the N. York State Agricultural Society, that the straw undergoing this process quadruples its weight, and assuming water to weigh about 8 lbs. to the gallon, (near enough for our present purpose,) we have some data upon which to found an estimate of the amount of water consumed in the Bommer process.

Thus 100 lbs. of straw produces 400 lbs. manure, having increased in the process 300 lbs., which at 8 lbs. per gallon is equivalent to 37½ gallons, which must be very near the amount absorbed.

Our own opinion is, that the straw more than quadruples its weight, but that it cannot quintuple it *from water*, is evidenced by the fact that the utmost absorbent capacity of 100 lbs straw in water is 43 gallons 3 quarts, which your correspondent will find by actual experiment.

Very respectfully your ob't. serv'ts.
ABBETT & Co.

AGRICULTURAL SOCIETIES.

It is a source of no ordinary gratification to us to witness the spirit which seems about to be aroused throughout the country on the subject of Agricultural Societies. It augurs well for the cause of improvement in this important branch of industry, and foretells with unerring truth the future prosperity of our country and its whole people.

The following proceedings at Eufaula, Barbour county, Ala., speak a language not to be mistaken, and exhibit a most laudable spirit in that young and prosperous country. Read, then, Georgians, and profit by the worthy example of your neighbors and brethren.

The Barbour County Agricultural Society met by order of a call from the President, at Eufaula, on 1st July, Maj. Snipes in the chair.

The object of the meeting was succinctly stated by Col. McDonald.

On motion of Col. Cochran, the following resolutions were adopted:

Resolved, That the Society accede to the proceedings of a meeting held at Glennville, on the —— day of ——, 1843, and cordially receive the members there added into the Society, and agree to have the meetings of the Society alternately at Eufaula and Glennville; and to the change then made in the time and place of holding the next meeting.

Resolved, That the Executive Committee of this Society be, and it is hereby, instructed to proceed to adopt proper means to have an Agricultural Fair some time during the ensuing fall, and report at the next meeting, to be held at Glennville on the 4th Saturday in the present month.

Resolved, That the Society look forward with

great interest to the report of the different Committees of the Society, appointed to examine the crops, as their reports will furnish valuable information to planters.

Resolved, That any gentleman or gentlemen appointed heretofore to examine crops in any particular beat or section of the county, shall be permitted to exchange duties with any gentleman appointed in a different beat or section, and when any one or more shall have been appointed in a section embracing his own crop, an exchange will be expected if practicable.

On motion of Mr. Flournoy, the meeting adjourned to the 22d inst. at Glennville.

A. McDonald, Ch'n.

Pitt Milner Caldaway, Sec'y.

THE ECONOMY OF FARMING.

Just as we were going to press, we received through the mail, from the publisher, a volume of 130 neatly printed octavo pages of the above title, translated from the German of J. Burger, Professor of Agriculture, &c. &c, with additional notes from several distinguished German professors, by E. Goodrich Smith. The late hour at which we have received it, precludes a detailed notice of its merits, and we therefore avail ourself of the testimonial of the Hon. H. L. Ellsworth, than whom no one is perhaps more capable of determining.

Patent Office, June 21, 1843.

Having advised the Rev. E. G. Smith to undertake the translation of a portion of Burger's Manual of Land-Husbandry, a text book in the schools and agricultural institutions in Germany, I take the earliest opportunity to commend the work to the American public. I have perused many of the pages, prepared for the press, and feel satisfied with the correctness of the translation, since the same has been submitted to a German scholar and agriculturist, Mr. Fleischmann.

There will be found, in this publication, many details and accurate experiments which the patience and zeal of the Germans have secured. This manual gives the precise information needed in this country, where theory is so often substituted for practice, and where large statements of products are given with so few items of expenditure, as taxes, oftentimes, the credulity of readers. With this manual in hand, enriched by numerous quotations from other writers, the youth of our country will grow up with accurate information on the great subjects connected with the profession. * * * *

Henry L. Ellsworth.

This is the first of what is intended to be a series of translations of Agricultural works, if the author is sufficiently encouraged. Price 50 cents.

Robertville, S. C., August 10, 1843.

Mr. Editor—I have a valuable horse, which, owing to a morbid state of the system, has been very much injured by eating dirt, whenever he can get it. Salt is kept by him, salted water is daily sprinkled over his food, poplar bark has been repeatedly given, also sassafras tea, but every thing has failed to do any good. Can you, or any of the correspondents of your valuable paper, furnish me with a remedy for this disease? A Subscriber.

We confess our inability to suggest a remedy for this singular affection of the horse of "A Subscriber." It evinces a morbidness of the stomach which we have never seen noticed before, and we give his letter to our readers with the hope that some one may suggest an efficient remedy.

AGRICULTURAL FAIRS.

Below we give a list of premiums offered by the Agricultural Society of Morgan, to be distributed at their Fair in 1844. It is a small beginning but a noble one, and we are taught by high authority "to despise not the day of small things." In our next we shall give a list of premiums offered by the Monroe Agricultural Society.

The managers of the Morgan County Agricultural Society offer the following premiums, to be awarded during the year 1844:

For the best acre of	Wheat		$3 00
" " "	Corn		3 00
" " "	Cotton		2 00
" " "	Oats		2 00
" "	Fourth of an acre of Sweet Potatoes		2 00
" "	Specimen of Ditching, for preserving hilly or rolling land		5 00
" "	Colt under 2 years old		3 00
" "	Milch Cow		3 00
" "	Bull		3 00
" "	Bull Calf under 2 years		2 00
" "	Heifer " "		2 00
" "	Boar and Sow under 2 years, each		2 00
" "	Piece of Domestic Cloth, 8 yards, for gentlemen's winter wear		3 00
" "	8 to 10 yds for a lady's dress		3 00
" "	Counterpane or Coverlid		2 00
" "	Specimen of Domestic Carpeting		1 00
" "	Specimen of Knitting		1 00

CURE FOR BOTS.

A writer in the Columbia (S. C.) Planter gives the following remedy for bots:—"As soon as symptoms of bots appear, raise the upper lip of the horse, and with the sharp point of a knife, scarify the inner coat of the lip (beginning at the top) making a number of slight gashes, transversely, causing it to bleed slightly. A case has never come under my own observation, (and I have cured many,) in which this simple mode of treatment did not succeed instantly. The most violent paroxysms will be relieved in five minutes. What connexion or sympathy there may be between the lip and maw, I leave to the curious and learned to decide.

WORK FOR AUGUST.

We have availed ourself of the labors of our brethren of the "American Farmer" and a correspondent of the "American Agriculturist," for the following calendar for August.

Briars, Bushes, Weeds and Shrubs.—If your fields, pastures, meadows or fence sides are infested with any of these enemies of cleanly culture, be sure to have them cut down this month, put in piles, and as soon as dry enough, have them burnt.

Draining and Ditching.—This is an excellent month to carry on these operations, and if you have any grounds that you cultivate, which may be too retentive of water, have them relieved by these means, as you may rest assured that by such relief you will add fully twenty-five per cent to their value, besides making them much easier to work.

Potatoes.—If you have not already given your late potatoes their last working do so forthwith; and be sure to lay them by clean of weeds, and that the top of the furrows be left as flat as possible.

Fallowing.—Get all your grounds intended for fall grain ploughed up as speedily as possible, taking care to get that alloted for rye ready first, as the earlier in September you get that grain in the better will it be; nor would we be content to sow it without spreading over every acre of the ground a bushel of plaster. With regard to the *time of sowing wheat* we are persuaded that most farmers delay that operation until it is too late. It is our opinion that every one should begin to seed from the 15th to the 20th of September. This would give the wheat plants time to get *well and strongly* rooted in the earth before the freezing of the ground in the fall, and thus serve to prevent the loss by freezing out. The only difficulty to result from early sowing is the fall attack of the Hessian Fly, but we think this may be obviated by watching the plants and rolling when the insect is in its chrysalis state; but even if this should not prove a *remedy*, the advantages to be derived by earlier ripening and consequent avoidance of the rust, would more than compensate for the hazards of the fly in the fall.

Sheep—As this is one of the months in which the fly deposits its eggs in the nostrils of the sheep, which produce the disease called worms in the head, and which destroy so many of these useful animals, we would advise you to avail yourself of a very simple and cheap remedy, one which we have often recommended and will here repeat. It is this: for every sheep, place in a trough, once a week, for five or six weeks, a gill of salt and as much tar. Place the tar on the bottom of the trough and spread the salt over it. In eating the salt the sheep will smear their noses with the tar, and thus secure themselves against the fly, as the aroma of tar is repulsive to his organs of scent. Besides protecting the animals against their insect enemies, the tar will act medicinally, and impart constitutional vigor to your sheep. But unless you intend to repeat the precaution *weekly*, don't attempt it at all, because in its repetition the security of the measure rests, and it would be but a mockery to do it once, and then ascribe its failure to save your sheep to the want of efficacy, when, in fact, your *own* neglect should be wholly chargeable with it. If you undertake to do a thing, do it as it ought to be done, and not by halves and quarters. If it is worthy of being done at all, it is worthy of being well done. We are of this fath: that whether a man be engaged in winning the smiles of a lovely woman, or farming, he should give to the object of his pursuit his whole heart, as nothing less than that should or will answer in either case.

Heifers.—All two year old heifers intended for milch cows should now be *served*, and in selecting a bull have a due regard to the improvement of their progeny. It takes no more to raise a good calf than an indifferent one.

Milch Cows.—When the pastures get thin, provide your cows with good succulent food of some kind, so that they may neither fall off in flesh nor milk.

Barn Yards, Cow Pens and Hog Pens.—Have these covered with loam and leaves from the woods, or mould of any kind, a foot deep, as your stock will convert every cubic foot of it into good manure before next spring. Don't say you have not got time to do it, but resolve that it shall be done, and the possession of the time will be an easy matter. For a farmer to say that he *has not time to provide food* for his crops, is a language which we do not comprehend; and our opinion is, that every man engaged in farming should teach every one about him to forget the meaning of the terms.

Make it a matter of especial attention to have every thing in readiness for picking cotton. It requires only the same time to prepare, and if done in time, you will have no detention. I therefore urge you to examine baskets, sacks, gin stand, gin band, running gear, presses, &c., and if anything requires repairing, do it immediately. Continue your improvements all spare time, such as grubbing, &c.; repairing fences about lots, repairing buildings, making shingles and scaffolds to sun cotton.

Cut crab grass hay, throw into heap-rows, there to remain for a day, then into tall narrow heaps until cured. Clean your potato plantings designed for seed or slips. Gather the fodder

from late corn. Thrash the grain designed for fall sowing, to provide against loss of time from cotton-picking, when the seed will be wanted, and that you may have the straw to pack away with the pea-vines, if you intend to same them.

Prepare turnep ground at once, if not done, a day or two extra work will not be missed 100 years hence, and you will be well paid. Procure Dale's hybrid turnep seed, and sow on the 15th, rain or no rain, Sundays always excepted. Sow half a pint of seed to the acre, any how, though old folks say a tablespoonful is enough; I would rather have a pint cup full. Unless the earth be wet, or decided appearance of rain, I would advise covering by brushing in: the last season taught me this. I had more turneps in half-a-dozen rows, where brushed, than on eight acres' where harrowed in. The ground should be made fine by frequent harrowings and plowings, then a brush rather settles the earth to the seed.

Bud peach-trees of this year's growth, the best if well cultivated. Procure buds from your neighbors, even if at a distance of 10 to 20 miles, to choice fruit; the same labor will grow a tree producing a delicious fruit, as one of those little tasteless hard things too often seen.

About the middle of this month, cotton will have sufficiently ripened and burst its covering, to permit your hands to average some 30 to 50 or 60 lbs. per day. When you can gather this amount get to it; you will save much of that which has opened from rain or injury, by hands passing between rows. Open the branches out to the sun, and a freer circulation of air causing it to open sooner, and not to rot for want of the sun to open it, and you will be the better able to keep up with the opening.

Top cotton early in this month, if not done the last of July.

EXPERIMENTS IN MAKING SUGAR FROM CORN STALKS.

The following, taken from the minutes of the transactions of the French Academy of Science, we copy from the American Farmer.

"At the sittings of this body in September last, a series of reports and researches was submitted by M. M. Biot and Soubeiran, on the subject of making sugar from Indian corn. It seems that, as far back as 1834, M. Pallas placed before the Academy an account of his having extracted two per cent of sugar—entirely like that of the sugar cane—from the stalk of the maize. M. Robiquet again reported upon Pallas' communication, suggesting that the greatest yield of sugar could probably be obtained immediately after the flowering of the plant, and that its quantity would be greatly lessened when the grain began to be completely formed. In 1839, M. Pallas again communicated experiments as to the effect, on the saccharine qualities of maize, of removing the ear at several stages of its growth. Upon this paper Messrs. Bouissingault and Biot again reported, pointing out the defects of M. Pallas' experiments, and indicating the proper method of investigating the matter.

"We give this little sketch of the progress of this conversion of maize to the purpose of furnishing sugar, as interesting to those who, in this country, are prosecuting the same object. Monsieur Biot's last paper is to the following effect:

" 'The stalks upon which they operated were taken from the Jardin des Plantes. Some of them had been separated from their heads, others had not. They report that the sugar of maize is precisely that of the sugar cane, mixed, however, with a small quantity of sugar of fecula. The juice of the maize which had been castrated, contained per litre, 113 grammes, or 12 per cent of sugar; that of the non-castrated gave 124 grammes, or 13 per cent. These experiments prove that castration is rather injurious than otherwise, and that if maize is to be used for the purpose of extracting its sugar, it must be in its normal state. Whether this new industry on an extensive scale would be a profitable one, is a question which, at the present moment, may be matter of dispute; but there is one consideration in its favor, supposing the productiveness of the maize to be such, if cultivated to the necessary extent, as to render the cultivation of the beet root unnecessary. The latter must remain on the ground during the whole of the summer, and the moment of harvest is too near that of the winter sowing for corn, to leave time to prepare the ground for receiving the new seed. Maize, on the contrary, runs through all the phases of vegetation in a few months, and it can be gathered in, as it is not necessary to leave it on the ground until it has attained to full maturity, and sufficiently early to have abundant time to prepare the ground for the winter corn seed. M. Thenard, one of the members of the Academy, alluding to that part of the report of Messrs. Biot and Soubeiran, in which it is stated that there is a small quantity of sugar of fecula mixed with the cane sugar of the maize, observed that the beet root contains crystalizable sugar unmixed with sugar of fecular, and that probably the presence of the latter in the experiments made on maize, was due to the mode of manipulation, and that it does not exist naturally in the plant.' "

GRASSES.

The following are some of the general results of Sinclair's observations:

1. Grasses which have culms with swollen joints, leaves thick and succulent, and flowers with downy husks, contain greater proportions of sugar and mucilage than those of a less succulent nature.

2. When this structure is of a light glaucous color, the sugar is generally in excess.

3. Grasses which have culms with small joints, flowers pointed, collected into a spike-like panicle, leaves thin, flat, rough, and of a light green color, contain a greater proportion of extractive matter than others.

4. Grasses which have culms furnished with numerous joints, leaves smooth and succulent, flowers in a spike or close panicle, florets blunt and large, contain most gluten and mucilage.

5. When this structure is of a glaucous color, and the florets wooly, sugar is in the next proportion to mucilage.

6. Grasses which have their flowers in a panicle, florets pointed or awned, points of the culm smooth and succulent, contain most mucilage and extractive.

7. Grasses with flowers in a panicle, florets thinly scattered, pointed or furnished with long awns, culms lofty, with leaves flat and rough, contain a greater proportion of saline matter and bitter extractive.

8. Grasses with long creeping roots, culms few, leaves flat and rough, flower in a spike, contain a greater proportion of bitter extract with mucilage.

In the first part of April, 1920 grains of the leaves of the following grasses, affording to Sinclair the following proportions of nutritive matter:

Meadow fox tail grass	96 grs.
Tall oat-like soft grass	120
Sweet-scented vernal	52
Round panicled cock's foot	80
Perennial rye grass	70
Tall fescue	94
Meadow fescue	96
Crested dog's tail	88
Creeping soft grass	90
Meadow cat's tail [timothy]	80
Fertile meadow-grass	70
Nerved meadow grass	76
Wood meadow grass	68
Creeping bent	42
Rough stalked meadow grass	80
Broad leaved red clover	80
White or Dutch clover	64
Great bird's foot trefoil	60
Long rooted clover	76
Lucerne	90

The chemical composition of the grasses varies materially in the progress of their growth. "I found," says Davy, "in all the trials I made, the largest quantity of truly nutritive matter when the seed was ripe, and the least bitter extract and saline matter; most extract and saline matter in the autumnal crop, and most saccharine matter in proportion to the other ingredients in the crop cut at the time of flowering."

Johnson's Farmers' Encyclopedia.

The Fort Gaines Whig of the 12th instant, in speaking of the growing crops in that section, says:—Corn crops are now made, and so far as we have been able to learn, they are generally good,—fully an average one. Cotton looks promising, but it is feared the late continued rains may cause it to rot; and we have already heard some farmers complain of its shedding the forms, which will, no doubt, be the case generally, should the wet weather continue much longer. The cotton crop is fully one month later now than of an ordinary year; so that, with circumstances altogether favorable from this time on, we can scarcely look for an average crop.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days.* And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent	$6
Farms up to 100 acres	10
" from 100 to 200 acres	15
" " 200 to 300 "	18
" " 300 to 400 "	20
" over 400 acres in any one farm	25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., AUGUST 30, 1843. No. 18.

MANURING, A SCIENCE.

If there is one department of agricultural science more neglected by the practical farmer than another, it is that of manuring. Chemists have made calculation after calculation, experiment after experiment, but all to little or no purpose. The farmer—I mean the working farmer—who is one from necessity, has derived little or no benefit from the host of eminent individuals who have concentrated their whole attention on agricultural chemistry. Why is this? Why is it that the great and all-important discoveries of Davy, are still laughed at by many—but slightly attended to by all; at least by all those who would reap the greatest profit from them? 'Tis true that a wonderful progress has been made in agriculture within the last few years; and much has been done in the improvement of stock, perfection of machinery, &c., but very little in the science of manuring. And the circumstance appears to be still more unaccountable when we call to mind the fact, that there are greater means of improvement in this particular branch of husbandry, than any other; in no other department are the rudiments so well understood and so generally circulated, as in this. We know the constitution of every agricultural plant; we have analyses of every description of soils; we are well versed in the respective compositions of air and water; we have abundant means of ascertaining the constitution of all manures; indeed, we know and perceive all but the peculiar operation of the vital principle, and yet we are daily applying matter to soils in which a sufficiency already exists. Why is all this? Why is it that in some departments agriculture is rapidly advancing—in others, making no perceptible progress? It is unpleasant, and by no means the choice of the writer, to give the cause of this anomaly; but 'facts are stubborn things,' and it becomes no one to conceal the truth.

It is well known that the improvements which have been made in stock, are owing to the exertions of *experimental farmers*, and those who farm for example; independent of which it requires little or no calculation to improve stock; there are no scientific rules to be pursued and committed to memory; it can be accomplished as well by a man of mediocre ability, as by one of a high order of intellectual capacity, provided he has perseverance. It must not be supposed, therefore, that no credit is due to those who have by their exertions improved the breed of any kind of stock. Credit is due to any one who confers the smallest benefit upon his fellow-creatures; but the purpose is to show why our breeds of animals have been so much improved, and another department of husbandry almost totally neglected. The cause, then, is that much in this respect has been done for the agriculturist, and there being little difficulty in what has been accomplished.

With respect to machinery, in which, perhaps, the most extensive as well as the most beneficial results have taken place, it need only be asked, who take the majority of prizes for machinery, at agricultural prize meetings? Not farmers, but machinists. This then speaks for itself; the improvements, the wonderful improvements made in machines, have been brought about by the machine venders, and not by farmers. It is readily admitted that it would be of no avail for machinists, &c., to construct new implements, if the farmer had no disposition to encourage their laudable exertions; still, it must be confessed, that the advance of agriculture in this department, is too little owing to agriculturists themselves.

The *true* signification of the word *science* is, a knowledge of all that *exists*, and of the laws that govern the operations of nature—a knowledge of matter, things and systems. Whatever is done by a system, is done scientifically; nature does nothing, except by the interposition of nature's God, without a system. A knowledge of these systems is science *generally*; a knowledge of any one system, *a* science. The numerous terms, the difficult rules, the complicated calculations, the mysterious analyses, are not *the science*; they are the handles, the guides, the agents which render the science comprehensible by human mind, invented by human beings for that purpose. They are the channels through which the Newtons, the Lockes, the Davys, the Liebigs, convey the researches of their expansive minds to unborn generations.—If science then, is a knowledge of the operations of nature, it must be from some unwholesome influence that so many individuals neglect to profit by it. The influence in the present instance, is *prejudice*—yes, prejudice—however disagreeable it may sound to those interested, it is too true; for what can it be but prejudice, that prompts men to say—"Our forefathers prospered without science, and why should'nt we?" What can it be but prejudice, which induces men to believe that the system they adopt, admits of no improvement?

In order to render the question more intelligible, it may be asked for what purpose do men apply manure to soils? Most assuredly to supply a something which is requisite to the growth of a plant, and which does not exist in the soil. Then, as we have the means of ascertaining what portiyn of the plant is supplied from the atmosphere, what from the rain which falls, and what from the soil, is it not evident that the slightest exercise of our reasoning faculties must enable us to judge with some degree of accuracy, what particular bodies or compounds should be added to the soil, in order that it may furnish the plant with due proportions of each of its component materials? If we once admit the possibility of the above statements—and who can deny that they are rational—we become advocates of science.

But in order to explain the subject more clearly, and that there may be no doubt as to the advantage of calling in the help of science in the application of manures—in making manuring a science, instead of an art, we will imagine an instance which has frequently occurred: two neighboring farmers enter upon the occupation of adjoining farms at the same time, and it so happens that they have adjoining fields of three-year-old turf; the soil in each field being composed, as far as ocular examination can detect, of the same materials. Being old friends, they make no secret to each other of the system of cultivation they intend to pursue; consequently, being convinced that some application is necessary to the turf, and having heard that nitrate of soda has had a beneficial effect upon such crops in many instances, they each decide upon applying this manure at the same rate per acre, and as nearly as possible at the same time. The result is, that a great increase in the crop is produced in one instance—in the other, no benefit whatever can be discovered. The consequence is, that the one individual denounces the use of nitrate of soda, the other applies it almost indiscriminately in almost all cases.—Meanwhile, this trifling circumstance probably engenders ill feeling between the old friends, and all because they cannot discover "a clue to the mystery." The foregoing is by no means an exaggerated picture of an every-day occurrence. This is the consequence of making manuring an *art*.

We will now suppose the same case treated scientifically—the parties being fully aware that a plant cannot abstract that from the soil which does not pre-exist in it. Their first impulse is either to submit a portion of the soil to the analytical examination of the operative chemist, or, being chemists themselves, to ascertain of what the soil is composed—the one individual finds it will be improved by the materials contained in the nitrate of soda—the other, not only that this manure will be useless, but what composition is required; now this is manuring *scientifically*; this is making manuring a *science*. The advantages of the latter system are obvious.

A little consideration, will, nevertheless, render it by no means remarkable that, notwithstanding the means of making the application of manure a *science*, have been long placed within the reach of agriculturists, yet that they have been utterly neglected; since it is generally known that the application of *artificial* fertilizers is comparatively of a recent date; prior to which period the evacuations of animals, combined with decayed vegetable matter, formed the staple manure of the country. Now *farm yard manure*, which was the chief application, contains every material that a plant requires; hence, if applied in sufficient quantities, it can never fail. But within a few years soils have been brought into cultivation, and those systems of farming have been adopted, which have compelled the agriculturist to introduce artificial manures, in order to supply the deficiency of nature. And from the circumstance that no artificial manures have been found, with one or two exceptions, to contain *every* material abstracted from the soil by plants generally, it is apparent that any one artificial manure is insufficient to maintain fertility in the soil. This renders it imperative upon the agriculturist to call in the assistance of chemistry, in order that he may be enabled to compete with other agriculturists; for if the soil requires phosphate of lime to produce a wheat crop, of what possible utility will it be to apply a manure which does not directly or indirectly afford that particular matter? And who can ascertain by mere ocular observation, whether the manure or the soil contains phosphate of lime?

If this problem cannot be solved by looking at the soil and the manure, what is the course to be pursued? We must endeavor to ascertain the composition of each, which cannot be done without the aid of science. It is very well to say, "Science was not necessary when my grandfather was a farmer." It is very well to say, "farmers have done well without science, and therefore it is unnecessary." But we must remember that our forefathers tilled the *richest* soil, at a time when farming produce realised almost double its present value, when receipts were larger and disbursements smaller, and

when they had abundance of farm-yard manure to preserve the fertility of soil, without resorting to the application of lime, nitrate of soda, and other mineral or artificial manures. Still it is by no means extraordinary that farmers of the present day, should be opposed to the application of scientific rules; or if not opposed to their application, at least careless in applying them; for, as they justly observe, farming has been conducted without science, and they cannot yet perceive the very different position in which they are placed, compared with farmers even of the last generation. The human mind is so subject to the unhealthy influence of prejudice, that it is no wonder farmers of the present day should be disposed to follow with almost invincible determination, the customs of past ages; yet, however natural it may be that they should thus act, it must be a source of sincere regret to the enlightened, unprejudiced mind, that they should thus be heaping up trouble for a future day.—*London Farmers' Mag.*

BOMMER'S MANURE.

Mr. Editor—The following communication I am sure will be read with interest by most of your subscribers, and as I have received recently so many intereogatories concerning "Bommer's Manure," I have concluded to send it for publication in the Planter, with such remarks as I may make upon it:

King William, July 6, 1843.

Mr. Woodfin—Dear Sir—I have seen the result of your experiment with Bommer's patent manure, in the last Planter, and while I believe every word you have said about, I am not entirely satisfied that it will be to the interest of every one to purchase the right to make and use it. Virginians have been so often humbugged with patent inventions, that I am very slow to receive any notion that comes secreted under a patent right, I will, therefore, be obliged to you to answer the following questions:

1st. Can the materials of which the manure is composed, and also those required to produce such speedy decomposition, be procured in sufficient quantities on a *poor forest farm* to make it an object on such a farm; or is it only adapted to the neighborhood of towns, where mincral, animal and other substances can be readily procured at little cost?

2· From the experiment you have made, do you think that labor may be profitably employed in making this manure on large farms, or is it merely intended for experimenters on truck patches, gardens, &c.?

3d. As the decomposition is so rapidly produced, does not the ammonia (or whatever you chemists call it, I mean the strength of the manure,) as speedily pass off, and the manure become comparatively worthless, as you have seen farm-yard manure become by being kept too long?

4th. You say it is not costly, but troublesome; how much and what kind of trouble is it? Is it that kind of trouble with which every successful farmer is acquainted, and for which he gets rewarded, more or less, or is it like the Indian's gun, costs more than it comes to?

5th. Taking every thing connected with it into consideration, would you advise a farmer owning some five or six hundred acres of poor land, situated twelve miles from navigation, and 30 miles from any town, employing the labor of twelve hands, and with a large and growing family, and not a cent to spend in humbugs or costly experiments, to purchase the right to make and use this mauure?

You will please pardon the liberty I have taken in addressing this communication to you; my only apology is my great desire to use all the means in my power, for the improvement of our mother earth, and I should like to become acquainted with this process of Mr. Bommer's, but do not like the idea of buying a pig in a bag.

Should you think it worth while to reply to this, you can do it through the Planter, if you prefer it, (as I suppose it probable you will receive other communications on this subject,) or by letter privately, by mail, as you may choose.

Yours, most respectfully,

Wm. S. Ryland.

In answering the foregoing queries, I shall take them up in the order they are propounded, without any farther preliminary remark.

1st. "Can the materials of which the manure is composed, and also those required to produce such speedy decomposition, be procured in sufficient quantities on a *poor forest farm?*" &c. &c. I answer yes—they can be procured in abundance, both for making the manure, and also for their speedy decomposition, with the exception of some articles necessary to make the lees.* The method is not adapted to the neighborhood of towns, except where large quantities of vegetable substances can be had.

2d. "From the experiment you have made, do you think that labor may be profitably employed in making this manure on large farms?" &c. Answer, I do. It is equally well adapted "to truck patches, gardens, &c." if they have an abundance of vegetable substances, not otherwise.

3. "As the decomposition is so speedily produced, does not the ammonia (or whatever you chemists call it, I mean the strength of the manure,) as speedily pass off?" &c. To this question I answer, in consequence of the great heat produced in the process of fermentation, it is quite probable that a portion of the ammonia may escape. Ammonia, however, has great affinity for water, and as a quantity of water is necessary in making the manure, I should think the escape of ammonia would not be very great. Mr. Bommer says "the salts produced in the process of fermentation, 'are a quantity of nitrate of lime and caustic potash, ammonia and saltpetre'—four substances which modern chemistry has found to contain the most fecundating properties possible."

4th. "You say it is not costly, but troublesome; how much and what kind of trouble is it?" &c. I alluded to the trouble of collecting the materials, making the compost heaps, making the "lees," and the several applications and waterings with the same, necessary to complete the decomposition of the materials. The labor thus expended I am sure would result in a rich reward to a skilful and persevering farmer. I must most respectfully ask to be excused from answering the 5th question. I will not advise any one to buy the right, lest for want of proper energy and skill on the part of the purchaser, it might fail to answer his purpose, and I should have the blame; I will, however, say this much, that from what I have heard of Mr. Ryland's zeal and energy in doing what he can to improve our "mother earth," that Bommer's patent could hardly fail of success in such hands. With him it would neither be like the "Indian's gun," nor the "pig in the bag."

In conclusion, let me remark, that I am no way interested in the sale of these patents—I own only an individual right, and should there not be another sold in the State it would be a matter of perfect indifference to me.

Very truly, yours,

Geo. Woodfin.

Southern Planter.

*The articles alluded to in the exception, which Mr. Woodfin did not consider himself at liberty to specify, are *lime* and *salt;* about fifty pounds of the former and a couple of pounds of the latter being required to an ordinary heap of the manure.—Ed. S. P.

Let every one cultivate flowers. They require little space, they furnish a tasteful and healthful employment, and contribute much to the happiness which forms the grand object of pursuit with all.—*Albany Cult.*

A princely mind will ruin a private fortune—keep the rank in which Providence hath placed you; and do not make yourself unhappy, because you cannot afford whatever a wild fancy might suggest.

Millwood, August 3, 1843.

Mr. Editor—You desire information as to the comparative merits of the Durham, Devon and Ayrshire cattle. Having tried all, I will give you the result of my experience, together with a brief history of the origin and the improvements of these celebrated cattle.

Until lately, there existed in England a great difference of opinion as to the superior breed, each having strenuous advocates. Since the very great and decided improvement of the short horns, effected by the skill, judgment and perseverance of Mr. Charles Collins, public opinion has awarded to this improved breed, the first rank, as possessing "a combination of perfections," hitherto attained by no other breed of cattle. The counties of Durham and York have long been celebrated for their short horns, of undoubted foreign origin, distinguished principally as extraordinary milkers. These cattle were large, coarse and deficient in the fore-quarter.

On the banks of the river Tees, they assumed a different character. "In color, they resembled the improved short horns, being occasionally red, red and white, and roan, though the last named colour was not then so frequent as now. They possessed a fine mellow skin and flesh, good hair, and light offal, particularly wide carcasses, and fore-quarters of extraordinary depth and capacity."

These latter Mr. Collins selected for his experiments, and by two or three judicious crosses upon them, and by proper selections, after these crosses were obtained, he established a breed which, for general excellence, has never been equalled.

It is much to be regretted that these experiments were conducted with as much secrecy as practicable, and that Mr. Collins should have declined, even after realizing a forture by the sale of his stock, to make known to the public the principles that guided him in producing such magnificent results. It is, however, known that his first step towards this improvement, was the breeding them down from a larger to a smaller animal, well aware that overgrown cattle are, almost necessarily, coarse. A single cross on the Polled Galloway, is supposed to have contributed most essentially to his success, as from it, in the fourth generation, Lady was produced, a cow occupying in the Herd Book as high a place as old Prunella in the Stud Book. The great object of Mr. Collins was, the production of a breed as nearly perfect in formation as possible, of early maturity, with a capacity to continue growing, and of great aptitude to fatten, without sacrificing their properties for the dairy. That he attained these objects is manifest, from the extraordinary prices he obtained for his stock, (having sold Comet, at 6 years old, for $5000,) and the avidity with which they were purchased, not only at home but abroad, and their rapid introduction into almost every portion of the civilized globe. Possessing the rare combination of qualities, hitherto considered incompatible, a great disposition to fatten, with high qualifications for the dairy, together with a carcass almost faultless, and of beautiful colors, these cattle could hardly fail attracting the attention of breeders. The Americans perhaps, of all foreign purchasers, have been the most liberal. Extensive importations have been made into the Northern, Middle and Western States, and a few of these cattle have been introduced into South Carolina. On the luxuriant pastures of Kentucky, they are in a state of progressive improvement. In the Northern and Middle States, they continue to maintain all their characteristic excellence. And in our State, with proper care of them, they exhibit, as yet, no degeneracy. They are large consumers of food, compared with our native stock, and require rich pasturage to keep them in high condition, but no breed of cattle will make greater returns, for extra care bestowed on them. Our dry and arid Sand Hills are unsuited to them, but any good cotton estate will support a few, enough for all the ordinary purposes of the plantation. Like all other cattle, they rapidly decline if turned

into the woods, half starved and utterly neglected. Such treatment is adapted to no breed, and least of all to an improved one. Mine have been kept during the spring and summer, in good pastures, on river low-grounds, having the run, in autumn, of corn fields, and in very bad weather they are fed on straw, shucks or hay. Under this treatment, I find they thrive very well, always looking in far better condition than the native cattle of the country. Such as are in use are, of course, highly fed, on boiled peas or meal, mixed with cut oats, fodder or hay.—Many of my cows have yielded thirty quarts a day; twenty is by no means uncommon.

On a future occasion I will notice the Devon and Ayrshires; to do so now, would exhaust your own, as well as the patience of your readers.

W. H.

Columbia (S. C.) Planter.

INDIAN CORN.

The great crop of the United States, whether we look at quantity or value, is unquestionably our corn crop. Four hundred and fifty millions of bushels in 1840, and probably five hundred millions in 1842, show the importance of this grain to us. And yet the quantity now grown is nothing, a mere drop in the bucket, compared with what we might do, should circumstances render it advisable to increase the production to an extent that might easily be reached on the present cultivated lands of the Union. In order to show at a glance what might be done, we have taken the pains to collect a few instances of good crops that have been grown among us, and would remark that on a very large portion of our soils, in favorable seasons, and with the cultivation corn should receive, crops like the ones named may be as well grown as inferior ones. It is true, we now and then meet with a farmer or writer, who asserts that no man ever saw 75 bushels of corn grown on an acre, and that the farmer should be contented with 25; but the only emotions excited by such, are contempt for the ignorant confidence shown, and pity that in this country men should be found so far behind the times.

The number of such crops where the product exceeded 100 bushels per acre, might be extended to a great length from the list in our possession, but the above is sufficient. Still we imagine some farmers will say, (some have said so,) that the man who puts manure and labor enough on an acre to get 100 bushels of corn is a loser. We would ask *how?* A man may cultivate an acre of corn and get thirty bushels an acre, and he will be a looser. But it is scarcely possible when the production is 100. In such a case, all over 50 bushels may be considered profit. In addition to this, his acre of land is placed in a condition to produce more good crops, and the additional amount of these is to be added to the list of profits. The man who has brought 30 acres of land to such a state that it will produce 100 bushels of corn per acre, is far better off than the one who has 100 acres, yielding only 25 bushels per acre; and of this fact we are happy to find many of our farmers are beginning to be well convinced. It is unnecessary to say the remarks we have made respecting corn, are equally applicable to any other grain or grass, and that the grand secret of success is to cultivate no more land than you can make rich.—*Albany Cultivator.*

SCRAPS FROM DE KALB COUNTY.

To the Editors of the Tenn. State Agriculturist:

GENTLEMEN—Tell the good housewives in Gath, to cook their sweet potatoes over a brisk fire; they are much more palatable and delicious when thus managed; whereas much of their flavor is lost by their being steamed over a lingering fire for a half day at a time before used.

THE DAIRY.

Every man that places any kind of an estimate on the comforts and luxuries of life, should furnish himself with a dairy; it should be well constructed and neatly managed.—Place boxes around it; fill them with rich earth and plant out hop vines in them; the vines will gracefully cover the dairy with their foilage, and completely shut out the beams of the summer's sun. How cool and refreshing are the contents of such a dairy! Then make yours like it.

PICKLE.

Take one gallon of whiskey and two of spring water and put them in a stone jar; put in your cucumbers and they will be ready for use in a few weeks, without any further preparation.—Try it. The writer, though, would be willing never more to taste a pickle, if whiskey could be banished from our beloved America.

BISCUIT.

The most wholesome biscuit I ever have eaten, were made of equal parts of wheat flour and that from flour corn. They are delicious and palatable. Try them.

GOURDS.

It is better to drink water from a gourd grown in Tennessee, than from a silver cup brought from London. Then cultivate gourds.

PRESERVATION OF HAMS.

The people in this mountain country, pack away bacon hams in ashes. The time of packing is early in March before the oil begins running from the effects of hot weather. A hogshead or barrel will answer as a place of packing, and the only precaution necessary, is to have the hams put up early and have the ashes dry, placing a layer of hams, then ashes, alternately. The hogshead should then be set in a dry place.

WHOOPING-COUGH.

Opossum's oil is said to be a sovereign cure for this painful disease. The patient takes it inwardly by doses after the manner of sweet or castor oil. Try it.

FOUNDER.

Bleed the horse freely, give him a half pound of salts, rub a small portion of spirits turpentine on at the top of his hoofs, force him to exercise, and he will be well soon. Founder is in the system at large, and not in the legs particularly; hence the efficacy of a purgative and bleeding.

FOOT-EVIL.

A. G. Alsworth, in a former volume of the Agriculturist, recommended boiling tar and tallow to be applied to the foot. I followed this direction, and found it a certain cure. Having tried it, I recommend it to others.

THE AXE.

The axe should weigh six pounds. This weight will, in general, suite all men that weigh from 130 to 160. It should be made with a heavy poll, a long blade, gradually tapering, with the lower corner a little the longer; the sides of the blade should be smoth and nearly straight, and the edge from corner to corner should be nearly straight. In grinding the axe, it should be laid flat on the grindstone, grinding from the eye downward; an axe is soon spoiled by holding it up in grinding, so as only to let a small space near the edge touch the grindstone. Collin's axes are styled by many, the best in use, but the writer it is hoped, will not be thought visionary for entertaining a different opinion. I have used several of them, and I never have found an easy chopping axe from the number. They are too light—have too small polls, and are too convex both on the sides of the blade and on the edge from corner to corner. An examination of the laws of motion, and the construction of the wedge will prove these assertions true. There is, however, one advantage in Collin's axes, and that consists in what the man said of his wife—"her is all temper." I don't see why we might not have all our axes made in our own State; for we have every necessary material at hand for their manufactory; and yet we must have them brought from New England. This reminds me of friend Kelp walking three miles to borrow meal for breakfast, when he might have gone to mill in half the time.

May the good people of this State not go in debt from this time henceforth; and when starving necessity compels them to buy, may they buy such articles as are manufactured in their own State. In view of this, it is better to use a tin cup of Tennessee manufactory, than a Liverpool glass—it is better to wear a tow shirt of our mother's make, than trans-Atlantic linen.—If the people would firmly conclude to live within themselves, to live at home, it would do more to prevent the influx of useless foreign merchandze, than all the tariff laws that stare through the ports from St. Johns to Sabine—manufactures would spring up, our streams would resound with the joyful voice of machinery, the farmer could get a demand for his produce, by furnishing the mechanic the raw material, and the mechanic in return could supply the farmer with manufactured articles. In conclusion, can there be any hope of prosperous times of long continuance until this is the case?

Can there be any hope of "easy times" until farmers can find a vent for their produce? and have they any unwavering assurance that they will find this vent until manufactories are established in our country?

Very respectfully,

DICK FORESTER.

Near Liberty, Tenn., July, 1843.

TO DESTROY WORMS ON CABBAGE.

GENTLEMEN—I am not aware that the following easy and simple method of destroying worms on cabbage, has ever appeared in print. I believe it was discovered by an unlearned person, and I hope will not be less efficacious on that account. As the worms are already commencing their depredations, it will be well to publish it soon.

At night (about sun down) strip off one of the lower leaves and lay it on the top of the cabbage, back side down. In the morning very early take it off, and the whole, or a large proportion of the worms of that cabbage will be on it, and can be disposed of as any one sees fit.—Two or three trials will effectually free the cabbage from all worms. I believe it never fails except when the nights are quite cool.

Respectfully, W. CHANDLER.

Tennessee Agriculturist.

ON DEEP PLOWING.

Deep plowing differs from ordinary and subsoil plowing in this—that its special object is to bring to the surface and to mix with the upper soil a portion of that which has lain long at a considerable depth, and has been more or less undisturbed.

The benefit of such an admixture of fresh soil is in many localities undoubted, while in others the practical farmer is decidedly opposed to it. On what principle does its beneficial action depend, and in what circumstances is it likely to be attended with disadvantage?

1. It is known that when a heavy shower of rain falls, it sinks into the soil, and carries down with it such readily soluble substances as it meets with on the surface. But other substances, also, which are more sparingly solnble, slowly and gradually find their way into the subsoil, and there more or less permanently remain. Among these may be reckoned gypsum, and especially those silicates of potash and soda, so useful to grain-bearing plants. Such substances as these naturally accumulate beyond the reach of the ordinary plow. Insoluble substances likewise slowly sink. This is well known to be the case with lime, when laid upon or plowed into land. So it is with clay, when mixed with a surface soil of sand or peat. They all descend 'ill they get beyond the reach of the common plow. Thus it happens that after the surface soil becomes exhausted of one or other of those inorganic compounds which the crops require, an ample supply of it may still be present in the subsoil, though, until turned up, unavailable for the promotion of vegetable growth.

There can be little question, I think, that the greater success which attends the introduction of new implements in the hands of better instructed men, upon farms long held in arable culture, is to be ascribed in part to this cause. One tenant, duriug a long lease, has been in the habit of plowing to a depth of three, or at most, perhaps, four inches—and from this surface the crops he has planted have derived their chief supplies of inorganic food. He has limed his land in the customary manner, and has laid upon it all the manure he could raise, but his crops have been usually indifferent, and he considers the land of comparatively little value. But another tenant comes, and with better implements turns up the land to a depth of 7 or 8 inches.—He thus brings to the surface the lime and the accumulated manures which have *naturally* sunk, and which his predecessor had permitted year after year to bury themselves in his subsoil. He thus has a new, otten a rich, and almost always a virgin soil to work upon—one which from being long buried, may require a winter's exposure and mellowing in the air, but which in most cases is sure to repay him for any extra cost.

Again, it is known that some districts, for reasons perhaps not well understood, are more infested than others with insects that attack the corn or other crops. These insects, their eggs, or their larvæ, generally bury themselves in the undisturbed soil, immediately beyond the ordinary reach of the plow. If they remain wholly undisturbed during the preparation of the soil, some species remain in a dormant state, and the subsequent crop may in a great measure escape. Plow the land deeper than usual, and you bring them all to the surface. Do this in the autumn and leave your land unsown, and the frost of winter way kill the greater part, so that the crops may thereafter grow in safety. But let this deep plowing be done in the spring, and you bring all these insects within the reach of the early sun, and thus call them to life in such numbers as almost to ensure the destruction of your coming crop.

IMPROVEMENT OF THE SOIL BY MIXING.

There are some soils so obviously defective in constitution, that the most common observer can at once pronounce them likely to be improved by mechanical admixtures of various kinds. Thus peaty soils abound too much in vegetable matter; a mixture of earthy substances, therefore, of almost any common kind, is readily indicated as a means of improvement. In like manner we naturally impart consistency to a sandy soil by an admixture of clay, and openness and porosity to stiff clays by the addition of sand.

The first and obvious effect of such additions is to alter the physical qualities of the soil—to consolidate the peats and sands, and to loosen the clays. But the fertility of a soil, or its power of producing a profitable return of this or that crop, depends in the first place on its chemical constitution. It must contain in sufficient abundance all the inorganic substances which that crop requires for its daily food. Where this is already the case, as in a rich stiff clay, a decided improvement may be produced by an admixture with silicious sand, which merely separates the particles mechanically, and renders the whole more porous. But let the clay be deficient in some necessary constituent of a fertile soil, and such an addition of siliceous would not produce by any means an equal benefit. It may be proper to add this sand with the view of producing the mere physical alteration, but we must add some other substance also, for the purpose of producing the necessary chemical change.

The good effects which almost invariably follow from the addition of clay to peaty or sandy soils, are due to the production at one and the same time, of a physical and a chemical change. They are not only rendered firmer or more solid by the admixture of clay, but they derive from this clay at the same time, some of those mineral substances which they previously contained in less abundance.

The addition of marl to the land acts often in a similar two-fold capacity. It renders clay lands more open and friable, and to all soils brings an addition of carbonate, and generally of phosphate of lime, both of which are proved by experience to be not only very influential, but to be absolutely necessary to healthy vegetation.

That much benefit to the land would in many instances accrue from such simple admixtures as those above adverted to, where the means are available, will be readily granted. The only question on the subject that ought to arise in the mind of a prudent man, is that which is connected with the economy of the case. Is this the most profitable way in which I can spend my money? Can I employ the spare labor of my men and horses in any other way which will yield me a larger return? It is obvious that the answer to these questions will be modified by the circumstances of the district in which he lives. It may be more profitable to drain—or labor may be in great request and at a high premium—or a larger return may be obtained by the investment of money in purchasing new than in improving old lands.

SALT AS A MANURE.

We know that plants require for their sustenance and growth, a certain supply of each of the constituents of common salt, which supply, in general, they must obtain from the soil. If the soil in any field contain naturally a sufficient quantity of common salt, or of chlorine and soda in any other state of combination, it will be unnecessary to add this substance; or if added, it will produce no beneficial effect. If, on the other hand, the soil contain little, and has no natural source of supply the addition of salt may cause a considerable increase in the crop.

Now there are certain localities in which we can say beforehand that common salt is likely to be abundant in the soil. Such are the lands that lie along the sea-coast, or which are exposed to the action of prevailing sea winds. Over such districts the spray of the sea is constantly borne by the winds and strewed upon the land, or is lifted high in the air, from which it descends afterwards in the rains. This consideration, therefore, affords us the important practical rule in regard to the application of common salt—that it is most likely to be beneficial in spots which are remote from the sea, or are sheltered from the prevailing sea winds.

This consideration, it may be hoped, will induce many practical men to proceed with more confidence in making trial of its effects on inland situations.

But some plants are more likely to be benefited by the application of common salt than others. Observations are still wanting to show which of our cultivated crops is most favored by common salt. Some crops may delight more in salt than others; and if we consider how much alkaline matter is contained in the tops and bulbs of the potato and turnep, we are almost justified in concluding that generally common salt will benefit green crops more than crops of grain, and that it will promote more the developement of the leaf and stem than the filling of the ear. If this be so, we can readily understand how a soil may already contain abundance of salt to supply with ease the wants of one crop, and yet too little to meet the demands of another crop.—*Johnston's Lectures.*

AGRICULTURE.

We are highly gratified at the increased interest now manifested at the South generally, on the subject of agriculture, and we trust the day is not distant, when it shall be seen in the Carolinas and Georgia, that we are able to make our own corn, raise our own mules, horses, cattle and hogs, as well as our numerous cotton bags. But if we would do this, we must abandon the ruinous practice, so long pursued among us, of wearing out our lands, throwing them away, and clearing more until all is wasted, and then decamping and seeking a new home among the fertile regions of the far West. We must improve our lands; we must, by improving our system of cultivation, learn to plant *less* and make *more;* we must, without extending our borders, increase our resources, and thus virtually enlarge our territory.

"He is a public benefactor, who, by the prudent and skilful outlay of his time and money, shall make a single field yield permanently a double crop; and he who does this over a square mile, virtually adds a square mile to the national territory—nay, he does more: he doubles to this extent the territorial resources of the country, without giving the State any larger territory to defend. All hail, then, to the improvers of the soil! Health and long life be their fortune—may their dreams be few and pleasant, and their sleep the sweet repose of the weary—may they see the fruits of their own labor, and may their sons reap still heavier harvests."

But if we would thus improve the soil, and so become public benefactors, we must become acquainted with the nature and character of our soil, and what sort of culture, &c., is adapted to its nature, condition, &c., and to do this we must read, yes, read as well as work; for whatever may be thought and said of "Book Farming" and "Theoretical Planting," we will find the following sentences to hold good in the main:

"Show me a thrifty, practical and experimental farmer, and I will show you a man who reads works on agriculture, or who borrows his hints from a neighbor who takes agricultural papers.

"Show me a farmer whose fences are going to decay; whose half-starved cattle are strolling over a brush field; and I will show you a man who, if he is not on the retrograde track, takes too little interest in agriculture, to patronize an agricultural paper."

But if we would read, we must take a newspaper: aye, that's the very thing we would recommend, for the borrowing system we never did like: take a paper yourself. "But this will increase my expenses!" Aye, true enough, it will from one to two and a half, or three dollars a year; but then of it increases the yield of your fields two fold, and makes you a richer, happier and wiser man, surely you will not be much the loser in the end.—*S. C. Temp. Advocate.*

Encourage youth to contend with and overcome difficulties.

Dr. Braxton, in an address before the Agricultural Society of King William county, Virginia, says:

That in all judicious systems of husbandry, the first step should be to establish a good rotation of crops. Different soils and different situations, of course, require very different rotations. He would, however, lay it down as "a safe rule, that no land ought to be put in grain cultivation more than half its time, that is, more than one grain crop should not be taken from land in two years, or two in four, or three in six years; and wheat should never follow corn; corn follows wheat very well, and oats succeed corn pretty well. But I would say, let clover follow corn without any grain crop whatever, as I believe the notion that it was necessary to have small grain to shade the young clover, is now pretty well exploded; as every observant farmer must have noticed, that wherever the fly had destroyed his wheat, the clover was much better than where it had been shaded and protected, as they call it, by a luxuriant growth of wheat; and that when the wheat was very luxuriant, the clover was generally killed." He speaks highly of the increased attention paid to the cultivation of artificial grasses, and particularly to that king of the tribe, red clover; of which he thinks there is now sown in King William county, a bushel of seed for every ounce that was sown but ten years ago! But still he notes it as among their faults, to have too great a surface in grain, and too little in grass. "All agricultural histories," says the Doctor, "both ancient and modern, prove that in proportion as that branch of husbandry has been attended to, that district of country has improved, and the proprietors have become independent, prosperous and happy." On the subject of manures too, he believes they are greatly deficient; they do not make as much as they ought, and might; and what they do make, they do not use to the best advantage. His "own experience goes directly in favor of top-dressing the year previous to the field coming in cultivation. But as a most judicious farmer says, put it on in any and every way you can, it will all do good."

The Doctor sets red clover down as the most valuable of all grasses. One good coat of that "I think is fully equal, if not superior, to any dressing of putrescent manure we can give our lands." He exhorts his brother farmers to meet every returning season with an increased energy and zeal in the good cause; and reminds them of the good old proverb, that "he who withholdeth not his hand from the plough, shall not want bread." He holds up the cheering hope, that by patient and persevering industry, and labor judiciously directed, we shall experience the best results—"certainly the doubling and tripling of the productiveness of our farms."

Orchards.—All orchards not in culture should have the hogs turned into them to eat the falling fruit. In doing so thousands and tens of thousands of the insectiferous enemies of the apple will be destroyed in their embrio state.—The trunks of the trees should also be rubbed thoroughly with a hard brush and then painted with a mixture of soft soap and flour of sulphur, in the proportion of five gallons of the former to one of the latter, and to make assurance doubly sure, lime (unslacked best) should be strewn pretty freely under the trees, not forgetting to sow with a heavy hand immediately around the trunks.

We often hear complaints made by farmers of the decay and death of their fruit trees, and to our mind the reason is obvious enough. It is *neglect*. Fruit trees, like animal and human bodies, have their enemies and diseases to contend against, and as they cannot doctor themselves, require that their wants should be supplied by their owners. If the treatment we recommend were resorted to twice or thrice a year, and orchards were not burthened with grasses or small grain, but subjected to row culture of some kind, we entertain not the slightest doubt but that even trees which are now enjoying a mere breathing existence, might be resuscitated into vigorous health, provided care were taken in judiciously pruning the decayed limbs and applying a proper composition to the wounds thus made.—*American Farmer.*

How to make an Unproductive Fruit Tree Bear.—A lady of our acquaintance took us into her garden a few days ago, where we were shown an apple tree which, she informed us, had been planted for ten or more years, but had never before borne any fruit. In looking over an old volume, she accidentally met with what purported to be a remedy for this unproductiveness, which was simply to cut from each limb, close to where it diverges from the trunk, a piece of bark about four inches round the limb, and one inch in width, and immediately replace it by tying it on with a rag until it adhered again. Early in the spring she tried the experiment upon the tree we speak of, leaving however two or three of the limbs untouched. The result is, that it is now filled with apples, which bid fair to ripen finely; but it is worthy of remark, that only on those limbs which had been cut is the fruit to be seen. The operation is very simple; and, as it has proved successful in this instance, we have no hesitation in recommending its trial in similar cases.—*Reading Gazette.*

Tomato Figs.—We copy the following from the American Farmer. It will soon be a seasonable article. The experiment has been tried in this quarter with the most satisfactory results. Rich specimens of the fruit thus prepared, were exhibited at the shows of the Cincinnati Horticultural Society this spring.—*Cin. Ga.*

Patent Office, July 10, 1841.

Dear Sir—The medicinal qualities of Tomatoes have greatly increased their cultivation, and every new preparation of the article is deserving consideration. A sample of "Tomato Figs" has just been deposited at the Patent Office, of a very superior quality. From the taste, I should suppose all the good qualities of the fruit are retained. In appearance, the drum of tomatoes resembles one of figs so nearly, that they might easily be mistaken for the same.

The sample is deposited by Mrs. Steiger of this city, and the recipe transmitted with it is enclosed for publication. It is deeply to be regretted, that since the periodicals of the day are open to communications, that so many valuable improvements are lost to the world barely for the want of publicity. Others may have dried the Tomatoes with a recipe, however, less successful. Very respectfully,

H. L. Ellsworth.

Hon. J. S. Skinner.

Take 6 lbs. of sugar to 1 peck [or 16 lbs.] of the fruit. Scald and remove the skin of the fruit in the usual way. Cook them over a fire, their own juice being sufficient without the addition of water, until the sugar penetrates and they are clarified. They are then taken out, spread on dishes, flattened and dried in the sun. A small quantity of the syrup should be occasionally sprinkled over them, whilst drying; after which, pack them down in boxes, treating each layer with powdered sugar. The syrup is afterwards concentrated and bottled for use.—They will keep well from year to year and retain surprisingly their flavor, which is nearly that of the best quality of fresh figs! The pear shaped or single tomatoes answer the purpose best. Ordinary brown sugar may be used, a large portion of which is retained in the syrup.

Lime Water for Worms.—Take six quarts of water, add half a pound of caustic lime, and after letting it stand a few minutes, commence watering the ground infested with worms, and they will soon be destroyed.—*Tenn. Agr.*

The whiteness of ivory handled knives may be restored by rubbing them with fine sand paper, or emery.

MONROE AGRICULTURAL SOCIETY.

The Annual Fair of the Monroe Agricultural Society will be held at Forsyth, on the second Wednesday in November next, when an Address will be delivered before the Society, after which the following premiums will be awarded by committees appointed for that purpose.

Competitors for premiums on crops will be required to produce certificates from one or more disinterested persons, of the amount of produce grown per acre, and it will also be desirable that they present a detailed statement of their mode of culture.

For the best acre of Corn on bottom land	$5 00
do do upland	5 00
Cotton on bottom land	5 00
do upland	5 00
Wheat, one acre	2 50
Sweet Potatoes, do	1 00
Turneps, do	1 00
The greatest quantity of cocoons, do	2 00
Best 10 yards of silk for lady's dress, a pair of Glass Pitchers.	
Pair of Silk Hose	1 00
Gloves do	1 00
For pound Sewing Silk	2 00
For 10 yards of Homespun for lady's dress, a Glass Pitcher.	
For 10 yards do. for gentleman's dress, a pair of Glass Preserve Dishes.	
For 20 yards of Negro Cloth	1 00
For 10 yards of Negro Blankets	1 00
For 10 yards of Carpeting	1 00
For 10 yards of Cotton Bagging	1 00
For Lady's Bonnet	1 00
For Hat	1 00
For Wool Hat	50
For best Stallion, 4 years old and upwards	10 00
For 3 do one year's subscription to the Turf Register.	
For Horse Colt 2 years old	2 00
For Brood Mare 4 years old and upwards	5 00
For Filly 3	4 00
For Filly 2	2 50
For Spring Colt	3 00
For Gelding	5 00
For pair Carriage Horses	5 00
For pair Mules	5 00
For Jack	5 00
For Jenny	5 00
For Bull	3 00
For Cow	3 00
For yoke of Oxen	5 00
For Ram	2 50
For Ewe	2 50
For Boar	5 00
For Sow	5 00
For Pork Hog, according to age	2 50
For litter Pigs between 6 and 12 months	4 00
For 6 months and under	2 50

Bradford T. Chapman offers a premium of a pair of Berkshire pigs for the best colt by Penndyer.

E. G. Cabaniss, Sec'y.

Cockroaches.—The following method of destroying these detestable intruders is simple and effective: Procure from the apothecary a small quantity of that odoriferous vegetable called poke root. Boil it in water until the juices are extracted, and mingle the liquor with good molasses; spread the mixture in large platters or soup plates; place these wherever the cockroaches visit, and the enemy will be found slain by fifties and hundreds on the following morning. A gentleman to whom we are indebted for this information, states that he slaughtered 575 cockroaches in one night, by the above process, and that the root which had been boiled being thrown into a closet thickly infested by the enemy, the place was quitted entirely in a few days, great numbers being left dead upon the field.

Boston Gazette.

To Destroy Bed Bugs.—Make a strong decoction of red pepper, when ripe, and apply it with a common paint brush to the joints of the bedsteads, wainscoting, &c., where these odious insects usually resort, and it is said it will soon destroy them.—*Tenn. Agr.*

WEDNESDAY, AUGUST 30, 1843.

BOMMER'S MANURE.

In our last we stated our impression that there was not an agent in Georgia for vending the rights to use this method of preparing manure. This notice has brought out Mr. Hardwick, of Sparta, to whose advertisement, in another part of this paper, we refer the reader. While on this subject, we commend to the reader's attention the communication of Mr. George Woodfin of Va., in which he gives his views of the method, and expresses his confidence in its success. We trust, however, we shall, ere long, be able to give the views of some of our own planters, who are now testing the system, and who have promised us the result of their experiments.

New Cotton.—The first bale of new cotton brought to our market this season, was received on Thursday last, from the plantation of Augustus Lamkin, of Columbia county.

A GOOD CROP.

From the Maryland *Telescope* we clip the following account of a crop of wheat raised by a citizen of Queen Anne's county in that State, to which we desire to invite the attention of our planters, as an evidence of the result that may be attained by an enlightened system of farming. The county of Queen Anne's is among the earliest settled in the State, and under the same system of agriculture pursued in Georgia, its lands would have been long since rendered unproductive and valueless. But instead of that we find her planters growing on land which has been cultivated longer than any lands in Georgia, larger crops than are produced on our best fresh lands. To what shall we attribute this? Certainly not entirely to the influence of climate, for there are many portions of Georgia and the Southern States admirably well adapted to the growth of wheat. Is it not more proper, then, and we put this question in all sincerity to every planter, that we should ascribe it to the miserably defective system of agriculture generally pursued at the South? We think so, and we feel fully persuaded that our readers will sustain this opinion—indeed, we are very confident no one will controvert its justice. Why then, we ask, is it so? Why are not our planters making the same progress in agricultural improvement with their brethren throughout the Middle, Eastern and Northwestern States?—These are imposing questions, and they may be easily answered. The great, perhaps the greatest, barrier to their progressive improvement is, they are generally too wise in their own conceit—they scout the idea that any man can learn them any thing about farming, because, say they, "*we have been farming all our lives, and we know that no man can teach us*—to suppose such a thing would be setting us down as stupid dolts, who cannot and will not profit by the light of experience." They have, therefore, an utter horror, a most perfect contempt, of what they are pleased to term "*book farming*," and cannot be persuaded to read an agricultural work.—One of the consequences, and the greatest evil of this ignorance on a subject which concerns them most, is that they are all struggling from the beginning to the close of the year to cultivate too much land—they are, therefore, in a continued strain—they have no time to devote to the improvement of land, but as rapidly as its fertility is destroyed by their exhausting systems of culture, instead of improving by manuring, their only remedy for the evil is to clear more—never having learned that the experience of all practical, enlightened farmers is, that it is cheaper to improve land than to clear it.—This is the great secret, and these are the great barriers to the improvement of Southern agriculture, and they are barriers of no ordinary magnitude—to correct which should be the object, the paramount object, of every patriot and friend of agricultural improvement.

Let then the Agricultural Societies throughout the country, as rapidly as they are formed, expose the fallacy of the system, and enforce with all their influence a corrective for the evil, and we will, ere long, record the growth of such crops in Georgia as the following, to which we alluded in the outset.

"Our respected fellow citizen, William Carmichael, Esq., raised this year upon twenty acres of land, *one thousand and twenty six* bushels of Mediterranean wheat, being a fraction below *fifty one and a half bushels to the acre*, averaging sixty pounds to the bushel. This is a very great yield, larger we believe, than was ever made before on this shore, and we question whether the State can beat it. This shows what *good farming* will accomplish.

"The land on which this wheat was raised, is not better wheat land than two thirds of this county, but has been greatly improved by the use of marl and marsh mud."

The Farmers' Cabinet says—One of our Maryland friends makes some inquiry in relation to the curing, &c. of corn that has been sown purposely for fodder. Among the advantages of this crop, when sown broadcast, may be reckoned its usefulness in soiling. For this purpose, it should be sown at different times, at intervals of ten days, or so. Some should be sown quite early in the season. It may thus be found to answer excellently in midsummer, when the pastures are short, and the drought would otherwise make green food scarce. When intended for winter fodder, it should not be suffered to become too old. It should be cut before the tassel appears—well and thoroughly dried—and when put away, it should have a peck of salt to the ton. We consider corn fodder more valuable for summer than for winter feeding. The Northern sweet corn, is perhaps the preferable kind to sow: the stalk is not so hard, nor so stout, and contains more saccharine matter.

COMMUNICATIONS.

Stanfordville, August 19, 1843.

Messrs. Editors—I propose to give in this communication, a few facts which I consider worth knowing, believing that some, if not all, the readers of your paper will, at some time, be benefited by the knowledge of them.

PREVENTIVE OF WORMS IN CHILDREN.

I think it likely that we have as healthy and as lively negro children as can be found any where in the State. They are never attacked by worms or any disease produced by them.—This desideratum is secured by a free use of tea made from the tops of the Jerusalem oak weed. As soon as it puts forth in the spring, we have it gathered some two or three times a week, and have a strong tea made of it, and sweeten it with molasses, in the proportion of about one pint of molasses to a gallon of tea. The children are as fond of it with their bread as they are of milk; in fact, they always seem to be pleased when they know they are to have tea for their breakfast, notwithstanding they have meat, milk, &c. This practice we keep up through the spring, and partially through the summer.

REMEDY FOR A FISTULO OR POLE EVIL ON A HORSE.

Take a common yard or toad frog between the fingers and thumb, and rub the diseased part with the belly of the frog. The water within the frog will soon escape and moisten the place which is being rubbed; but the operator must not stop rubbing till the frog is to all appearance dead. Rubbing once a day for three or four days, I have never known to fail effecting a cure, if commenced before matter had collected. An old gentleman from North Carolina gave me this information fifteen years ago. He said he had known it tried for forty years, and had never known a failure if well attended to, and had known several cures after matter had collected.

KIDNEY WORMS IN HOGS.

We sometimes have a hog or hogs to become weak in the loins, and finally drop their hind-parts, without being able to raise them again, which, when they move, are dragged along.—This, in ninety nine cases out of one hundred, is produced by what is called kidney worms. To prevent this, or to effect a cure after a hog has (as we say) broke down, requires nothing but a free use of coperas dissolved in water and mixed with meal so as to form a dough. It will require some six or eight doses to cure a hog after he has got down. All farmers should give this preparation to their hogs several times in the spring of the year—in fact, it is good for them occasionally through the year. I had a hog down last year, dragging itself about for several days before I gave him coperas, which after I commenced soon effected a cure, and he was on his feet again. Coperas will destroy the large worms frequently found in the bowels of a hog, as well as those that are in the kidneys. One ounce or less is enough for a hog at a time, and given once a day is enough in any case. Sulphur is also good for hogs, and

enough of it will make them shed lice if they have any, and may be given without any risk of danger; or at least if there is danger in giving it, I have never found it out.

TO PREVENT RABBITS FROM BARKING YOUNG FRUIT TREES.

Mix sulphur and any kind of grease (perhaps hogs lard is the best) together, and rub it on the trees from the ground fifteen or eighteen inches up, all round. After being once rubbed it will never require repeating. When I was a boy, my father had a young apple orchard, (in Virginia,) to keep the rabbits from barking the young trees of which, it fell to my lot to tie broom straw round them every fall, until he was told to have sulphur and lard mixed together and rubbed on them. It was also my duty to prepare and make the application. It had been done about twenty years when I last saw the orchard, and there never had been a tree touched by the rabbits after the application was made, and by rubbing my hand on the trees where the application had been made till it was warm, I could distinctly smell the sulphur.

I am, sirs, yours respectfully,

JOHN FARRAR.

CULTURE OF WHEAT.

GREEN COUNTY, August 8, 1843.

Messrs. EDITORS—Your notice of the sample of wheat I sent you by the hands of a friend that was passing, in the Cultivator of the 19th of July, is now before me, and though I am not in the habit of penning communications for publication, I comply with your request therein made, and shall write as though I were talking with you in my cabin, or walking with you through my fields.

You stated that you would be glad if I would furnish an account of the character of the soil, its preparation, time of sowing, reaping, and last, though not least, the yield.

The soil is inclined to be red, though somewhat mixed with sand. The ground was last year in corn, which did not make me more than two and a half barrels to the acre. After removing the stalks, I had about six small loads of lot manure hauled and spread over the ground, which was thirty yards square. I then plowed it up with a common rooter, and let it remain so for ten or fifteen days. I then sowed about eight bushels of cotton seed, and at the same time (which I think was the 10th of December,) I sowed the wheat, broadcast, and then plowed it in with the same kind of rooters.—Nothing more was done with it until the 2d of June, at which time I reaped near two thirds of the ground, and the balance a few days afterwards. The rains, which continued for several days, injured the wheat some, and having it to change and move about, much was lost. I sowed but a small quantity, (as I stated to you,) which was an eighth of a bushel lacking a pint. From this I saved and measured five bushels and one peck, and I think I must have lost near two bushels.

Having answered your enquiries in a short way, allow me to make a few more statements which may be somewhat necessary to accompany the above note. The wheat alluded to was handed to me the last of November, by a friend in Athens, who said it should be sowed in October, and stated that the gentleman who was so kind as to send him the sample from which this was made, had been cultivating the same kind of wheat for twelve years, and that he had never seen the least appearance of smut, nor even the rust. From the small sample I sent you, you will see it is a large and fine grain, which I think would have been improved had it been sowed in the month of October. I have been sowing the little white wheat for a number of years, which is a forward wheat, perhaps as much so as any we are in the habit of cultivating. My last crop was sowed in the month of October, on the same kind of soil, under the same fence, and with the same preparations, and the wheat sowed in December was reaped at the same time, and if the grain were the same, in which there is no comparison, I would prefer the kind sent you, for I think there need be no danger of the rust, it being a very forward wheat. I am yours, &c.

A PLANTER.

MAKING SOAP.—Among other things, let me tell you to learn how to make soap. I do not know that I should have thought of naming this, if my ignorance of soap making had not troubled me exceedingly. At first I did not know the method, and depended on the old woman who lived with me, to make it. I went to her when the soap keg was almost empty, and told her we must have some made as quick as possible. "Why, law! Miss, now don't you see it ain't the right time of the moon?" I tried to persuade her that soap making and the moon were but very slightly connected, if the other part of the business was well conducted. It was, however, to no purpose—I had to wait till the "right time" came round, before I could get my soap. After this, when I had the superintendence of a large family, I was obliged to buy it by the barrel, because I did not well understand the manufacture of the article, and I was really ashamed that such extra expense was caused by my ignorance. Sometimes there was too much lime with the ashes; then again not enough: sometimes it was too greasy, and sometimes any thing but what it ought to be. I tell you my experience in the matter, so that you may learn from your mothers *now*, and not have the trouble of *learning*, when you ought to be making it. As I have given you so long a talk on the subject, I will add a recipe I found in the Cultivator. It may be of use to some of your mothers, if not to you. Mr. Tomlinson writing to Judge Buel, says: "My wife has no trouble about soap. The grease is put into a cask and strong lye added. During the year, as the fat increases, more ley is stirred in, and all occasionally stirred with a stick that is kept in it.—By the time the cask is full, the soap is made ready for use. It is made hard by boiling and adding a quart of fine salt to three gallons of soap. It is put into a tub to cool, and the froth scraped off. It is afterwards melted to a boiling heat, and a little rosin or turpentine given, which improves the quality."

Some of you will think me a most unsentimental sort of a woman, when I advise you to learn how good bread, butter, coffee, pickles, puddings, &c., are made; but you will have to learn sometime, or do worse. Work with your own hands too, even if it should tarnish their whiteness a little. A man does not consider the beauty of a soft white hand a very strong recommendation, when he finds it has been kept for show and not for use. I think a young lady should be able to scour a kettle and grace a diamond.

LUCY.

Michigan Farmer.

AGRICULTURAL SOCIETIES.

The following remarks of the Columbia (S. C.) *Planter*, on the important advantages to be derived from Agricultural Societies, are so just and proper that we cannot omit the opportunity to urge their consideration upon our readers, and we sincerely hope they will not permit such valuable suggestions to pass unheeded.

"The benefits resulting from these associations, we think, are not properly appreciated in many portions of the country.

"Agricultural Societies are eminently useful in a moral and in a pecuniary light. They excite a greater interest in devising and carrying out improvements, that otherwise might not be forced upon the attention of their members.—And thus, by inducing planters to feel more interested, a spirit of inquiry is created, which leads them to devote more time to profitable reading, than would otherwise be the case. No one who is accustomed to meet with his neighbors three or four times a year, and listens to the details of their experiments, and to the practical information which they suggest, can be indifferent to his own improvement. A planter thus stimulated to seek information on a subject, of which *knowledge is power*, becomes not only a more intelligent and thinking man, but he becomes a more practical and successful agriculturist. He finds more time to read, and less to waste in idleness and dissipation. Interested in some system of improvement he has formed—home has fresh charms for him, and his farm receives a greater share of attention. These we regard as moral advantages, resulting from Agricultural Societies, of no small consequence. And we think it can scarcely be denied, that if associations of this kind do impart this stimulus, they must tend, also, to the pecuniary improvement of their members. If *mind* is at all concerned in successful agriculture, surely whoever is stimulated, no matter by what, to improve in a knowledge of his profession, and who applies that knowledge to its practical details, must acquire greater skill. And if he does this, he necessarily reaps a pecuniary reward, exactly proportioned to his increased skill. In agricultural pursnits, there is no professional jealousy, for the success of one is not at the expense of another; and surely, if there is any avocation, in which the knowledge of each should be the common property of all, it is in that of the planter. By means of Agricultural Societies and Agricultural Papers, this is effected.—They condense the scattered rays of knowledge that, separately, afford but feeble and uncertain light, into a common focus, where they are combined and reflected back on all. The reading of one, the reflections of another, and the information derived from experience in a third, thus become the reading, the reflections and the experience of all. Hence Agricultural Societies are the cheapest and most effective agricultural schools that can be instituted, while they promote, at the same time, a social intercourse among neighbors, that contributes, in no small degree, to the pleasures of life. We will not dwell, however, on these social advantages.—Estimate Agricultural Societies by the amount of actual information which they cause to be brought forth and diffused. If they are conducted with proper spirit, committees are appointed every year, each to consider some specified subject, and after gaining all the information in their reach, to report this information for the benefit of all the members. Each member of a committee should give his views, the result of his experience on this one particular subject, and his opinions as to any prevailing practice connected with it, and the reasons for those opinions—from these the chairman should prepare his report, and submit the condensed knowledge of the whole committee. If we suppose that a very large amount of practical knowledge will not be elicited in this way, we must sadly underrate the capacities of our neighbors. There are rich mines of knowledge throughout

the country, which need only to be brought forth o give southern agriculture a higher stand than it has ever enjoyed, or ever, in fact, deserved to enjoy. This information, however, like gold, is not found in any one place in large masses. It is scattered in minute particles among the great mass of agriculturists, and to make it extensively useful and valuable, it must be collected particle by particle, submitted to the refining fires of reason and experience, and then condensed for general circulation. To collect these scattered particles, to test their value, to condense and circulate them for the common benefit, is the great object of Agricultural Societies. And that this is a practicable object, has long ago been proved, by the improvement in knowledge and in practical skill, among the members of those societies that have been conducted with even a tolerable share of energy and spirit. Can the Southern country exhibit a greater number of well informed, skilful and successful planters, than is to be found among the members of the Wateree and Monticello Agricultural Societies? We particularize these because we happen to know the character and success of the members of these two societies, better than we do those of most others. We presume that none of them would deny that they owe much of their respective improvement to the direct and indirect influence of these associations.

"We cannot drop this subject without again urging planters, generally, to exert their influence in forming and sustaining these societies throughout the State, and let them make the State Agricultural Society the common bond of union."

WHOLESOME TRUTHS.

Keep it before yourself, young man, that industry and good morals will be a passport for you in good society; and will make you respected and esteemed by the good and wise.

Keep it before yourself, young lady, that kindness of heart, a sweet disposition and an even temper, will make you an agreeable companion with the old and the young.

Keep it before yourself, young man or woman, that in a choice for a partner for life, you should look well to the habits and disposition of each other. That a young man with a cigar in his mouth, and cane in his hand, and his brains running to hair, may do very well for a beau, but is not to be compared to the plain, unpretending youth, whose heart is right, and whose common sense will not allow him to play the dandy.

That young lady who is all accomplishments, who can sing a little, dance a little, thumb the piano a little, and look fascinating at any time, may fill a place on the sofa, and be the belle of a ball room, yet if she cannot boil a pudding, roast a steak, dust a room, or darn a stocking—if her accomplishments are all for show and none for use, then ten chances to one, that the young lady who has got a knowledge of household affairs, who has been brought up by a careful mother, and is well learned in the actual duties of life, will make a better wife, and a pleasanter and a happier home.

Keep it before yourself, farmer, that you should return to the earth at least as much as you take from it—that you should make your land richer each year, nor let it wear out—that you should have a neat house, large barns, good sheds for your cattle, and show that it is your ambition to make "two spears of grass grow where one grew before."

Keep it before yourself, merchant, that a "nimble sixpence is better than a slow shilling;" that one price for goods or dealing with every person alike, is the right way to give general satisfaction; and that to secure customers and trade, you must advertise freely.

Keep it before yourself, mechanic, that punctuality is a virtue; that work promised, should always be done at the time, and well done; and then you need give yourself no fears of a want of business.—*Exchange paper.*

RECIPES.

Messrs. Editors—The following are the recipes obtained in Maryland, to which I alluded in my last:

Recipe for Dyeing Green.—Take ½ lb. of oil vitriol, 2 oz. indigo—put in a bottle and let it stand three or four days; shake it well every day; then boil a strong liquor of hickory bark; dissolve 2 lbs. alum in water, put 6 lbs. yarn in the alum water, pour all the ingredients into the dye, put it all on the fire, and boil it well. The same dye will then color 6 lbs. more of a paler green. After it is dyed, and dried, it must be washed out with good soft soap.

To Dye Red with Red Wood.—1 lb. red wood, (hacked,) 2 oz. alum, powdered; the red wood must stand twenty-four hours in river or spring water; then boil it well, and after straining, mix your alum and aquafortis, and boil it well for several hours. Mix 1 oz. aquafortis, 1 oz. block tin, in a tumbler, and set it in the sun about one hour. The above will color 2 lbs. of yarn. After being dried, wash out with soft soap.

To Dye Pink.—2 oz. cochineal, ½ lb. cream tartar, 1 lb. alum, the whole put in a kettle of soft water; then put in 6 lbs. clean yarn, and boil it well; not to be washed after being dried. I saw several very beautiful carpets that were dyed with the above recipes, and for brilliancy of color, they would compare with the finest Turkey. I was particularly struck with the substantial appearance of one carpet, and on inquiry, was informed that the filling was entirely cow's hair, carded and spun by hand; the cost was but a trifle, and a more durable looking carpet I never saw. I think the whole filling of cow's hair, all white, did not exceed two dollars for a whole carpet. Persons near a city would do well to turn their attention to the manufacturing this article, as it has generally been deemed useless. A small quantity of cow's hair, with the inferior and coarse wool, would make a carpet that would outlast any carpet that could be bought: and in these hard times, every thing that tends to economy should receive attention. Politicians may rant as much as they please as to the why and wherefore, and settle the *cause* of hard times among themselves, but when they come to the *remedy*, they will find that nothing but industry and economy will afford relief.

Yours, respectfully,
George W. Craven.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, Jr.,
No. 232 Broad street, Augusta, Ga.
August 30. 18–tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18–tf WM. HAINES, Jr.

BOMMER'S PATENT MANURE.

THE undersigned is the Agent of Messrs. Abbett & Co., for vending rights to individuals for making and using the above named Manure. By reference to the following advertisement of Messrs. Abbett & Co., the prices may be ascertained. All orders addressed to me, *post paid*, at Sparta, Ga., will receive prompt attention.
Aug. 30. 18–tf R. S. HARDWICK.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days.* And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent $6
Farms up to 100 acres 10
" from 100 to 200 acres 15
" " 200 to 300 " 18
" " 300 to 400 " 20
" over 400 acres in any one farm 25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.

PRIZE ESSAY.

THE PREPARATION AND USE OF MANURES.

BY WILLIS GAYLORD.

INTRODUCTION.—Of all the pursuits to which mankind, from necessity or inclination, have devoted themselves, there is none more honorable, certainly none more useful, than that of agriculture. To pursue this business successfully, knowledge, extensive and varied, is required; for although a man may succeed by following the beaten paths of his predecessors, occasion will frequently arise, when the end desired may be attained by methods much shorter than those usually adopted, if the farmer is able to form and apply them. It is here that science has, within a few years, rendered the most essential aid to agriculture. Sometimes, reasoning from well known effects to their causes, the agricultural chemist has placed in the hands of the farmer the means of producing results, always desirable, but which, under the older systems of farming, with its utmost care, he frequently failed of obtaining. Again, taking well established facts in animal or vegetable phisiology as his starting point, he has arrived at results of the highest practical importance, and is enabled to render more certain and effective the more tardy operations of nature. In no department of agricultural industry, it is believed, have the labors of science been more beneficial or more apparent than in that of the preparation and use of manures; certain it is, there is no department more deserving attention, or where an elucidation of the principles and laws that govern the growth of plants, acts with a more direct and energetic influence.

DEFINITIONS.

A definition of the term manure, may be necessary, in order to treat the subject understandingly, as different individuals use the word in widely different senses, some in a wide, and some in a limited one. A few instances of the meaning put upon the term will be given from a few of the modern writers who have adverted to this topic. Thus Dr. Leiber, in his German Conversationes Lexicon, defines manure to be "vegetable, animal and mineral matters, introduced into the soil to accelerate vegetation, and increase the production of crops." The Encyclopedia, published by the London Society for the Promotion of Useful Knowledge, thus defines it:—"Every substance which has been used to improve the natural soil, or to restore to it the fertility which is diminished by the crops annually carried away, has been included in the name of manure." Loudon, in his great work on agriculture, says—"Every species of matter capable of promoting the growth of vegetables, may be considered as manure." Professor Low, in his Elements of Agriculture, says—"All substances, which when mixed with the matter of the soil, tend to fertilize it, are in common language termed manures." Mr. Johnson, in his "Farmer's Encyclopedia," lately published, says—"A manure may be defined to be any fertilizing compound or simple ingredient added to a soil, of which it is naturally deficient."—The definitions of Prof. Liebig and Dr. Dana, two of the latest writers on the subject, do not differ essentially from those already given. Of these definitions, I prefer the most simple and comprehensive, that of Loudon, and in this paper shall consider the term manure, as embracing every substance capable of promoting the growth of plants.

CLASSIFICATION.

Manures, by some, are classed as earthy, organic and saline; others divide them into animal and vegetable, mineral and mixed manures, and some speak of them as composed only of geine or humus and salts. Others class them as organic and inorganic; but these divisions are of little consequence, as every farmer understands that manure is the result of decomposition or change; and that, whether organic, that is, derived from animal or vegetable matter; or inorganic, such as the earths, clay, lime, the alkalies, &c.; it is only efficient when presented to plants in certain forms, such as decomposition, division or solution. In France, they have terms to distinguish those substances which act mechanically in improving the texture of the soil, from those which act directly in the nourishment of the plant. The former class of substances they call *amendments*, and the latter class *engrais*. It is probable, however, that the system which considers all manures as consisting of humus or geine, and salts, comprehending, in the latter term, all the mineral substances that enter into the growth or nourishment of vegetables, will effectually be found the most simple, and at the same time the most accurate of all the proposed divisions of manures. Thus humus constitutes the source of the carbon, forming the principal part of the structure of plants, and the salts, where they do not enter into the structure of plants, are active in preparing the other inorganic elements, and exciting the vegetable organs in their reception and appropriation of nutriment.

HUMUS OR GEINE.

Humus or geine is simply decomposed animal and vegetable matter; and as from it, by the action of oxygen, carbonic gas is derived, to be absorbed by water and taken up by the roots, or mixed with the atmosphere and taken up by the leaves of plants; or, as some agricultural chemists with good reason suppose, is under certain circumstances dissolved, or is soluble, and thus rendered fit for immediate nourishment to plants, it must be considered the most important item in the production of manures. The salts, which are the most efficient in aiding vegetation, or the most active manures, are those formed from the alkalies and their various combinations.—Thus, from pure lime or calcium, is formed, by the union with carbonic acids, *carbonate of lime*, with phosphoric acid, *phosphate of lime*, the base of bones, one of the most efficient of fertilizers; with sulphuric acid, *sulphate of lime*, or gypsum the value of which is well understood; and so with the other alkalies, which, in their combinations, form substances of the utmost consequence to plants. It is well known that the outer covering of some kinds of cane, contain so much flint or silex as to strike fire with steel; and some of the grasses contain this substance in such quality that their ashes will melt into glass with potash. Now, this hardness, so necessary to their perfection, could not be attained unless this flint had been rendered soluble by union with an alkali, forming a silicate of potash, and by this solubility been rendered fit for the action and appropriation of the plant.

FOOD OF PLANTS.

If we would know what kind of food is required by plants, one of the first steps necessary is to ascertain of what the plants themselves are composed. The combination of matter may be said to be absolutely endless; but the original elements of this multitude of combinations, are few in number. Chemistry has detected only some fifty-five substances incapable of further reduction, or what are called simple substances; and of these, strange as it may appear, only four, except in proportions merely accidental, go to the formation of plants. Of these the first is *Carbon*. This forms from 40 to 50 per cent by weight, of the plants cultivated for food; and is therefore most important to animals and to man. The second of these simple substances, is *Oxygen*. The quantities of this substance are immense; and though we are acquainted with it only in the form in which it exists in the air, nearly one half of the solid crust of the globe, 21 per cent of the atmosphere, eight pounds in every nine of water, and more than one-half of the living bodies of all plants and animals, are oxygen. *Hydrogen* is the third substance peculiar to plants. This is the lightest of known substances, and forms a small part of the weight of all animal and vegetable bodies; constitutes one-ninth part of the weight of water, but enters into the composition of none of the masses that go to form the crust of the globe, coal excepted. The fourth simple substance, entering into the formation of plants, is *Nitrogen*. This forms 79 per cent of the bulk of the atmosphere, constitutes part of most animal and some vegetable substances; is found in coal to the amount of one or two per cent, but does not exist in any other of the mineral masses constituting the crust of the globe. Although not an abundant substance, the importance of it is not the less decided, and some of its functions are of the most indispensable kind. Plants then, are composed of carbon, oxygen hydrogen, and nitrogen; the first derived from carbonic acid, the second from the atmosphere, the third from the decomposition of water, and the fourth from ammonia absorbed by water, and taken up by roots of the vegetables. Some of the earths are occasionally detected in plants, and salts of some kind are always present. In the preparation of manures, the principal object to be aimed at, it is evident, must be to supply the materials needed to furnish the carbon and the ammonia; and these are found in the greatest abundance in dead or decomposed animal and vegetable matter.

LAW OF NUTRITION.

It seems to be a law of nature, that the higher the grade of the animal, or the more complicated its organization, the greater the necessity of a corresponding degree of organization in the substances used as food; indeed the matter in which the crude materials, found in the earth and almosphere, are worked up by plants into a state suitable for conversion into the flesh of animals or food for man, exhibits the strongest proofs of benevolent design in the formation of such grade of organized matter. Man can, indeed live, live on plants, but his teeth demonstrates that flesh was to constitute no inconsiderable portion of his food. As all animals receive their food, either directly or indirectly, from the vegetable kingdom, it is evident their excrements, or their decomposed bodies, must form manures of the most valuable kind; and and it is to this source, the excrements of animals, that the farmer must look for his supply

of manures to restore the fertility of the soil. In treating further of manures, it will be best to begin with this, as the most important class.

ANIMAL MANURES.

A late British writer on agriculture, says—the chief use of cattle on an arable farm, besides those necessary for the operations of husbandry, is to produce manure for the land. If the cattle repay their food, and the expense and risk attending their keep, the manure is sufficient profit. Even with a moderate loss, they must be kept, when manure cannot be purchased. The loss, if any, on the cattle, must be repaid by the increase of the corn crops. Manure is to a farm, what daily food is to an animal; it must be procured at any sacrifice."—Common barn-yard or stable manure is the kind to which most farmers must look for the fertility of their farms. This consists of the droppings of the cattle, mixed with the straw used for littering in stables or thrown into the yards for the animal to feed or lie upon, the coarser hay and weeds refused by the stock, and the urine of the animals kept in the stables or yards. This is constantly trampled, is usually kept moist if not wet, and is finally decomposed, or converted into manure fit for the production of crops. This is the most usual course, but it is evident that there must, in this method, be a serious loss to the farmer, of the more valuable properties of the manure. In this way, the decomposition is unequal; a part will be converted mould while the other will be scarcely acted upon; the salts and the more soluble parts of the excrements, which are the most efficient ones, are dissolved by the rains, and carried off by the drains, or lost in the earth; and where any considerable degree of heat is evolved, as there will be when the decomposition is rapid, or is going on in large masses, the escape of ammonia, so easily detected by the smell, shows that the nitrogen, so essential to the growth and perfection of a grain crop, is rapidly wasting.

PREPARATION.

To prevent these results, and secure the whole benefit of the manure, two methods have been adopted. The first consists in applying the manure fresh, or in a long state, to the fields it is wished to manure, without waiting for it to decompose. In this way the manure collected in the yards during the winter, is removed in the spring, and applied to such crops as require it the most; and as no fermentation ensues in ordinary cases, until the commencement of hot weather, two sources of loss at least are avoided, those of the washing away of the soluble parts, or their being carried off in the shape of gas. Where there exists no necessity for retaining manures for other than spring crops, and where crops cultivated are such that long manures are suitable for their growth and tillage, this mode of disposing of manures must be considered one of the best that can be adopted. But in many cases the formation of manures in the yards and stables of the farmer is going on the whole year; and preservation in masses, or by being scattered in yards during the hot months, would be to greatly lessen, if not mostly destroy its value. Besides, there are some crops, such as some of the root crops, in the cultivation of which experience has proved fully that rotted or decomposed manure is far preferrable to long manure, as much of it is already in a soluble state, and is available to the plants at the time they need hastening the most, which is the period immediately after germination. When the waste of manure is to be prevented during the summer months, or it is desirable to provide a quantity of fully rotted manure, then the second method should be used; and this indeed, by many excellent farmers, is considered the best in all cases.

FERMENTATION.

In this method, the practice is to remove the dung from the stables and yards at short intervals, and place it in large piles or masses, that the proper fermentation may take place previous to its use. When a pile of manure is made in this way, the fermentation takes place in the quantities applied, as they are successively deposited, and therefore does not reach usually that point in which material loss is sustained. If it is found that the heat is becoming too great, or the fermentation injuriously rapid, so as to cause the escape of ammonia, a layer of earth or sods placed over the pile, will retain, by combination, the escaping gases, and thus prevent the loss. It has been found a most excellent plan, one which not only greatly increases the quantity of manures made in this way, but adds to its quality, to mingle with or cover the successive deposits of manure with earth from ditches or ponds, peat or muck from swamps, or turf from bogs or plowed lands, as such layers, consisting mostly of vegetable or animal matters, will by absorbing the drainings of the manure, or the absorbtion of the escaping gases, be converted into one of the most efficient of fertilizers. The more solid such deposits of manure are made, the more slow will the fermentation be, and hence in unloading, the carts or wagons may be driven over them if necessary to expedite the work, where the immediate use of the manure is not an object. Should the dung placed in these heaps be too slow in fermenting, it may be hastened by opening the piles, or still better by making a hole in the top, into which the wash of the yards and the urine of the stables may be poured. This method has another advantage. The manure from the yards if not wanted as long manure, may be removed to the fields where it is to be used, at times when the men of the farm cannot be otherwise profitably employed, and will be at hand, ready fermented in these piles, when a further transportation might be difficult if not impracticable.

LONG OR ROTTED.

It is a question of considerable importance to the farmer, and one which has been much discussed, whether it was better to apply manure in its long state always, or always allow its full decomposition before using. From his own experience, the writer has been led to doubt the correctness of either of these positions. It seems to be universally admitted that matter, to be efficient as a manure, must be soluble, and it is clear that the more solid parts of farm yard manure require to be softened by putrefactive fermentation before they can be considered in this state. When, then, the influence of manure required to be felt at once, as on the turnep, beet or carrot crops, in order to push them forward at the first start beyond the reach of insects, my experience is, that the manure should be in a state reducible to powder, in which condition a large portion of it may be expected to be soluble, and of course at once available by the plant. Where, during the fermentative process, the mass has been reduced to a black carbonaceous matter, it may be inferred that the heat was too great, and the manure seriously damaged; on the contrary, if the mass, while pefectly fine, dry and friable, still retains its dark brown color, it will usually be found that none of the good qualities have been lost by over-fermentation.

But where the manure is to be applied to crops which do not require forcing forward in the early part of their growth, but demand as much or perhaps more nutriment at a late period of their vegetation to perfect their seeds or roots, than experience has shown that it is best to apply the manure without any considerable fermentation to the soil. Indian corn, potatoes, and he grain crops generally, are of this class; the two first particularly. The time when corn and potatoes require the most nutriment, is at the time when the ears and tubers are forming; and when manures but partially fermented, or used fresh from the yard or stable, are applied, the decomposition is comparatively gradual, and the supply greatest when most needed. I cannot recommend the application of manures of any kind directly to grain crops, as it has a tendency to give straw at the expense of the grain, and wheat so manured, is far more apt to suffer from mildew or rust, than when the manure, by application to other and previous crops, has become perfectly incorporated with the soil. In this state, that rapid growth, which the result of first fermentation, is avoided by the wheat plant; and the substance necessary to perfect the berry are already prepared and within reach of the growing or maturing plant.

Dung varies much in its quality, not only from the perfection or imperfection of the fermentation to which it is subjected, but also from the animals producing it, and the food which animals receive. The richest and most effective manure we have ever used, was that from the hog yard, and produced by fattening hogs. That from cattle, fed on corn meal and oil cake, will be little inferior; and either will be found 100 per cent better than ordinary farm yard manure. The reason of this is very plain. Such animals are fed with substances abounding in the materials most needed by plants, with very little admixture of useless matter, and the comparatively small quantities of animal matter and salts added, rather contribute than detract from its efficacy. The dung of sheep is more valuable than that of horses or cattle not fattening, as the materials are more perfectly assimilated or mixed in mastication, and more fully decomposed.

GREEN CROPS.

Next to farm yard manures, to keep up the fertility of his lands, the farmer may most certainly rely on green crops, either fed off upon the land, or turned under by the plow, and there allowed to ferment and decompose. For a plant to enrich exhausted soils, affording as it does both top and roots to a large extent, there is no plant equal to clover; and particularly where it is necessary or desirable to have the green crop fed off by animals. I prefer letting the clover grow until nearly or quite in blossom, and then turning sheep upon it. They will eat much of it and fatten rapidly; but they will trample down more, and mixed with their dung forms in its decay a most efficient top dressing; and repeated for two or three years, forms an admirable preparation of the soil for wheat or other grains. When a crop is cultivated to be plowed in, it should be done at the time when the plants contain the greatest quantity of nutritive matter, and have least exhausted the soil in which they are growing. This, in most cases, will be when the plants have come fully into flower. At an earlier period there may be as much weight, but a larger portion of it will be mere water; and if allowed to stand much later, the soluble matter is lost in the seed, and the ligneous part of the stem becomes more difficult of decomposition. Buckwheat is a good plant for a green manure; its growth is rapid, and gives a great weight per acre, and two crops may be plowed under in a year. The best way of plowing in such green crops, is to pass a heavy roller over them, which lays the plants close to the ground, and greatly facilitates covering them by the plow. It is believed that corn, sown broadcast, and when just showing its tassels, cut and covered by the plow, would be one of the best crops that could be chosen for this purpose. A man or boy in this case, would be required to follow the plow, to place the corn in the furrow for covering, at the next passage of the plow. Taken at this time, corn abounds in nutritive matter, and could scarcely fail of proving a first rate fertilizer of the soil.

PEAT.

A variety of decomposed vegetable matters, or those partially decomposed, are used as manures. The fallen leaves of trees are of this class; but the instances are few in which they will repay the expense of gathering; perhaps never in the United States, where the other sources of an abundant supply of manures are so numerous. If collected, the best method of using them, is to litter stables, or form beds for pigs, or mix at once with other manures; as in such ways, they absorb urine and other fluids that might escape, and together undergo decomposition. But the most important source of decayed vegetable matter, and one, the value of which is not yet by any means sufficiently un-

derstood or appreciated, is to be found in the great deposits of this substance in swamps, low meadows, and peat bogs, in all parts of our country. On the subject of this kind of manure there is no authority equal to Dr. Dana, of Lowell, Mass. According to him, peat consists of soluble or insoluble geine or humus, with a few salts. From an analysis of ten specimens from different parts of Massachusetts, the highest and the lowest in the scale of soluble geine, is selected and given here, as well as two specimens of pond mud. This is done, as the value of neither peat or such mud is sufficiently appreciated by the farmer; and they are neglected when they might easily be made a source of the greatest fertility:

	Soluble Geine.	Insoluble Geine.	Total Geine.	Salts and Silicates.
Peat.	10.15	49.45	59.60	40.40
	48.80	43.60	92.40	7.60
Pond mud.	5.10	8.90	14.	86.
	8.10	6.50	14.60	84.40

COMPARISON WITH COW DUNG.

In his analysis of various manures, he takes for his standard cow dung; and it is not a little remarkable that the constituents of peat and cow dung should so nearly coincide. Dr. Dana's estimate of the several parts of peat of average quality, and of cow dung is as follows. The peat was fresh dug, in this case; before, it was dried at 300°.

	Peat.	Cow Dung.
Water,	85.	83.60
Salts,	1.	95
Geine,	14.	15.45

PEAT COMPOSTS.

But notwithstanding this decayed vegetable matter is so rich in the organic elements of plants, experience proves that, applied in its natural state, it is almost valueless as a manure, compared with stable manures; and hence the reason it has been so little prized. Science has shown the cause of this result, and the means of obviating it; or in other words, of unlocking the fertilizing powers of these vegetable deposits. To be able to give out ammonia, the peat or swamp muck must be fermented; and this may be effected by the direct addition of alkalies, or by making the peat into a compost with fresh manures. If alkalies are added, the quantity necessary to bring a ton of fresh peat into the same condition, so far as regards ammonia, as cow dung, would be "92 lbs of potash, 61 lbs. of soda, or 16 to 20 bushels of common house ashes." But the farmer will usually find the best method of using peat, will be to combine the peat with manure, by mixing it with dung in his yards, or making it into compost. Many experiments have been made by some of the best farmers and gardeners of Massachusetts, in relation to the use of peat; and all unite in pronouncing it most valuable. Mr. Phinney, of Lexington, says, that "a cord of green dung converts twice its bulk of peat, into a manure of equal value to itself; that is, a cord of clear stable dung, composted with two of peat, forms a manure equal in value to three cords of green dung." Mr. Robbins, of Watertown, though owning a large stock, makes no use of their manures. These he sells; but keeps his farm in a high state of fertility, by mixing swamp muck or peat with spent ashes from his soap and candle factory. The proportions he uses are, one part of spent ashes to three of peat, dug up in the fall and mixed with the ashes in the spring. After shovelling over two or three times, it is spread and plowed in. The effect is felt at once; and so far the manure has proved durable.

(To be continued.)

SAVE YOUR SOAP SUDS.—There is scarcely a plant that is not benefitted by watering with soap suds. It furnishes nutritive matter as well as moisture; keeps off insects, and promotes a rapid growth. The Gard. Chronicle states that while there has been a great failure in the cabbage and cauliflower gardens generally, those watered with soap suds have produced plants of the finest quality, and entirely escaped the injuries inflicted by insects upon others.

CRUSHING CORN—CORNSTALKS.

MESSRS. GAYLORD & TUCKER—I do not intend passing another winter without a corn and cob crusher. During the winter of 1840-41, I hauled my corn to a bark mill, run it through, and then hauled it ten miles to a grist mill, and got it ground coarse, and never but in one instance did I get my grist without going twice for it. This you will say was paying dear for the whistle, and so it was; but I thought it paying dearer still, to see my working cattle voiding unmasticated, full one-half the corn they ate.

In 1841-2, I hauled my corn to a steam mill in town, and paid one-sixth for toll, besides paying $5 to get the thing started; and I foddered 26 head of cattle and young horses on cornstalks cut up at the roots before frost, on to which, after being run through a patent cutting box and well wet, was put from two to four quarts per day to each head, of corn and cob meal. My cows gave milk all winter, and nearly up to calving; and all my neat stock, with one or two exceptions, would, if any accident had happened to them, have been ready for the butcher.

I saved $400 in wintering my stock, admitting hay to be worth $14 per ton, which was the case here that winter. I have a portable horse power, which I think will turn the crusher, and stormy days in winter, my help can be employed in grinding, instead of keeping under the feet of the women, who must necessarily be employed about the house. Yours, truly,

Maumee City, O., 1843. J. W. SMITH.

P. S. Will the gentleman of Hereford Hall, please favor me and the public, through your paper, with the particulars respecting his mode of raising calves, and especially the manner of making flax seed jelly, from the beginning until it is ready to feed. Will ground oil cake do as well?

Albany Cultivator.

USE OF SALT.

MESSRS. EDITORS.—I see it stated that common salt, (muriate of soda,) is coming into use largely in England, as a manure. We have around a salt manufactory at this place, a large quantity of refuse salt, with which we could very easily test its virtues. I am however, ignorant of the quantity per acre used on land, and of the mode of using it; also on what soils, and on what crops it is found to be the most beneficial. Any information on this subject will be gratefully received. S. F. VINTON.

Athens co., Ohio, 1843.

In England, salt is generally applied to the wheat crop, and is spread on the fallow, "some time before sowing in quantities of not less than ten, or more than twenty bushels per acre." The use of salt does not appear to increase the bulk of straw, but the ear is better filled, and the grain plumper and heavier. Another mode of applying salt, is to take quick lime and slake it with strong brine. This should be done a month or two before it is required for use, and then mixed with swamp muck, or earth, before spreading on the soil. Lime so prepared, is said to produce a capital effect. From the experiments made, it appears that light or gravelly soils, are those most benefitted by the use of salt.—*Albany Cultivator.*

CLOVER.—The impression in this region is general that Clover cannot be successfully cultivated. The secret of cultivating this crop consists in *deep ploughing, careful sowing* at the proper season; and the judicious *shading* of the tender plant from the early heat of the summer sun, until its tap root has struck so deeply into the earth as to reach the point of perpetual moisture. The soil must have a clay foundation, so as to retain water—it must be well cultivated, loose and free from other grasses. It must be productive and well limed, or plastered. It ought to be sowed 20 lbs. to the acre, on a wheat crop, after that grain is fairly set, and during the winter months. Thus it will be protected until the month of June, after which it should by no means be pastured until the second year.—*Augusta Washingtonian.*

MILKING.

That a mineral loss is sustained by the dairyman, from the manner in which the process of milking is usually performed, there is no doubt. In milk, the most valuable part is the lightest, as we see from the cream rising to the surface of the vessel; and it is reasonable to suppose that the same relative position is maintained in the udder as in the pan or pail; that is, the cream or richest part is in the highest of the lacteal vessels, and of course, is the last to be extracted in milking. When this operation is carelessly performed, or, in other words, the cow is not milked clean, the best part is left in the udder, and lost to the dairy. It may be said, however, that what is left at one time is obtained at another, and is not therefore lost, but it must be remembered that the process of absorption is constantly going on, and that by leaving the richest part for this action of the vessels, it is irrecoverably lost; and besides, the more completely the vessels are emptied the greater the secretion will be. I do not approve of this dripping or stripping, as it is called; for the quicker a cow is milked and milked clean, the more milk she will give. All dairymen are aware of the fact, that to dry a cow, nothing more is necessary than to only partly drain her udder at each successive milking, that is unless we leave off entirely. I do not speak without knowing. We have had hired help for several seasons past, and they generally milked, and it was enough to have worn out the patience of man in waiting for them to milk their number of cows. I don't wish to be understood that all are alike, but in too many instances it is the case. The milker should be instructed to milk as fast as his strength will allow; and the idle or slow milker would at once be discharged from this branch of the dairy. While some will milk from twelve to fourteen cows an hour, others do not, I won't say cannot, milk more than eight cows an hour. I have had experience enough, although young, to know something about milking, and how quick a cow can be milked. It is by attention to minute things that most of the profits of the farmer are realized, and we are confident that by attention to this point, non-essential as it may appear, the dairyman would find an important addition would be made to the sum total of his annual profits.

WESTERN.

New York Farmer.

FLAX SEED.—OIL.—The Genesee Farmer says great attention has been paid this year to the culture of Flax Seed in Western New York, for the purpose of making oil. In Seneca county alone, more than 1000 acres have been put down to flax, solely for the sake of the seed. Several oil mills are now erecting in that quarter.

The oil makers furnish seed for sowing in spring, and contract with the farmer for the crop when harvested, at $1 per bushel. The yield is from 10 to 15 bushels per acre: and farmers find the crop more profitable than wheat or oats. It is sown early in spring, on good dry land, half a bushel of seed per acre. It ripens in August, and if raised merely for the seed, is harvested and thrashed like other grain. But when the stalk is used, it is pulled up by a machine as soon as the seed begins to ripen, and bound in small bundles, the seed stripped off by a machine and the stalks spread out and dew rotted. It is then sold to the hemp makers for $7 or $8 per ton; which is said to more than pay for all the extra trouble. An acre yields about one ton of stalks. When the land is in good condition, wheat is commonly sown after flax; but this will not answer on poor land.

MAXIMS.—Never expect your lands to give you *much* if you give them *little*; nor to make you *rich* if you make them *poor*.

To 'save at the spigot and let out at the bung,' will soon empty the largest hogshead, so will economy in small matters and waste in large ones, speedily squander the largest estate.

MANAGEMENT OF FRUIT TREES.

Messrs. Editors—The article in the June number of the present volume of your paper, headed the Peach Tree, requires some notice, and probably a much more extended one than my time will admit of at present. In the first place, allow me to say, that the disease of the peach tree, called and known as the yellows, is not contagious, and I will hold myself ready to prove, not theoretically or speculatively, but practically, that there is no such thing as a healthy peach tree being infected by another, standing adjacent and having the yellows. I will not say that this or any other disease cannot be innoculated; but if it can, I have not been able to do it in several experiments made for the purpose.

I will endeavor to detail some of my experiments and observations in regard to the yellows, &c., and believe that I can show it to be the result of error in their culture. This farm had upon it in 1836, a small apple orchard, the trees standing at distances of 32 feet; between the rows of apple trees, peach trees were planted at distances of 16 feet, tree from tree. The peach trees were in a very unhealthy condition, some of them being in the last stage of the disease called the yellows, ceased to live after that year; others not so bad, but having the disease in its worst form, every part of the tree being affected, received my care and attention. My first desire was to get rid of the peach worm, which I readily accomplished by the use of salt and saltpetre around the trunks of the trees, &c., and at the same time I gave to those trees producing good fruit, a top-dressing of manure. In 1838–'39, my orchard was entirely free from the worm, and appeared in a healthy condition, with the loss of only three trees out of about forty that had the yellows.

The orchard being in good health, I resolved to test my then theoretical views; having planted a few trees to supply me with fruit, in case these should be destroyed, I went more cheerfully to work and selected eight trees standing in a row, had the ground manured for about ten or twelve feet on each side of the row of trees; it was then ploughed, and potatoes were planted in every third furrow, this furrow receiving an additional quantity of manure. The balance of the orchard was ploughed during the month of September; a part thereof received a dressing of manure and was ploughed in; another part was manured after being ploughed, and a third part without manure; the whole orchard was sown with wheat, and the following spring with clover. The effect was that a large majority of the peach trees showed some symptoms of disease, but more perceptible on those where there was no manure, where the manure was turned under, and where the potatoes were planted. Of the eight trees where the potatoes were planted, I was resolved on saving four of them if possible, for here I thought the greatest amount of injury was done, (though I have thought differently upon the subject since,) yet in this case the injury filled my fullest expectation, and the four trees unattended to had the yellows and were about to die, when Mr. J. L. McKnight and a friend of his, both living in or near Bordentown, New Jersey, and both peach growers, came to see my orchard; these gentlemen, pointing to three of these trees, asked if I could cure them, I told them it might be possible, but they were very far gone; their remark was that they thought these trees could not be restored to health. The middle one of these three trees being most diseased, was selected by me to be cured, and if Mr. McKnight and his friend will call and see me in September next, I will promise to give them some perfectly sound fruit, to be gathered from this tree, tho' the fruit is not of a very good kind. The other two trees died for want of attention, and were cut down this spring. Now this is one instance, of which I have ample testimony, of this disease being curable; though it is not the first instance of cure with me by very many. The disease was produced by the plough, and the cure by rest, with a top-dressing of stable-manure and ashes.

I deem it unnecessary to say anything more about my orchard at present, but beg your indulgence to permit me to ask attention to the effect produced from ploughing orchards. A person living within two miles of me has an apple orchard that was, to within the last three years, a most prolific orchard, but in consequence of some of the trees putting on the appearance of decay, he thought that to manure it and plough it would it would be of service; this he did three years ago, and the orchard producing no fruit the next year, and the trees appearing more unhealthy, he manured and ploughed again; but still he has no fruit, and his trees are growing worse instead of better. Another person about seven miles distant, has an apple orchard that he had worked in corn three years ago; one of his people being at my house the following year, I inquired if there was any fruit on the trees: "No! the frost has killed all the apples." I then asked him about trees standing in different parts of the orchard, where I knew they could not plough, and was told that these trees were full of fruit and that the "frost did not hurt them." I desired him to say, the next time he was asked why these trees were full of fruit and the others not, that they could not injure them with the plough. I could give very many instances of this kind, but my object being to call attention to this matter, I will ask every one to make his own observations and comparisons; let every farmer look into his neighbor's orchard and his own, and see what the effect of ploughing is when compared with the unploughed orchard adjacent to that ploughed; let him call to recollection the fine orchard planted by his father, that is going into decay, and ask himself the cause, and he will receive more knowledge upon this subject than could be derived from volumes written upon orchards, though I would strongly recommend the perusal of all works written upon the subject of our business, the avocations of life are always promoted by a proper and strict inquiry after truth, and no agent should be neglected to the advancement of so desirable an end.

My system is to work a tree just as I do the corn plant; the one is an annual, the other is a perennial; give the tree all the cultivation it is to have while young, and before a set of organs are wanted for the perdurable formation of fruit, and when the tree puts on the appearance of premature decay, I give to it a coat of manure spread upon the surface of the ground; this I apply in the fall of the year, always preferring long to short manure, and when ashes are deemed necessary, I have put them on in the spring.

Shall I say a word here about peach trees 30 or 40 years ago, which Mr. Downing represents to have grown anywhere in the United States, south of forty-three degrees of latitude. Well, forty years ago there was but little demand for peaches as a market fruit, and they were for the most part converted into pork and brandy. For these purposes it did not answer at that period of time, to pick them off the trees by hand, but a neat grass lay was considered as indispensable to facilitate their collection, as step-ladders are at the present day. The peaches then were shook off the trees, and the best selected either for drying or the still, and hogs disposed of the balance.

There were several reasons why orchards were not destroyed at the time by tillage, and perhaps the most prominent one was, that a grain crop in the orchard would prevent or retard the gathering of the peaches, which, by the by, were worth more than any grain crop that could be grown in the orchard; but whenever an old peach orchard was ploughed a few times, a new one had to be planted, or at least such was the case 30 years ago, on some farms, to my certain knowledge. I do not wish to be understood that the peach tree can be grown at the present time with the same facility it could then, for I have no doubt that the pabulum necessary for the support of this tree has become in a great measure exhausted from the soil, but I presume it can be restored; if so, we must get "the neighbors" to resuscitate their soils, and to form a good stock by proper tillage; but when the trees come into full bearing, we must then feel satisfied with whatever nature may be pleased to do in the premises, for any stirring of the soil after this period of growth is obtained, has a tendency to bring the orchard into decay, of which I can show hundreds of surviving witnesses.

A careful inquiry will show that the peach tree began to decline about the close of our last war with England; grain commanding a very high price at that time, peaches were only considered in a secondary point of view; and orchards that probably had not been disturbed with the plough for 15 or 20 years previous, were then put in wheat, corn, &c. This soon brought the orchard into decay, and in many instances they were not replaced; and when replanted, they have been treated very differently from the original. We must now have a crop of grain, grass or roots, but in former times such things were not expected from a peach orchard, after it began to produce full crops of fruit.

You have told us how to plough, manure, work and embellish our lands, to gather and secure our crops, with a long list of etceteras, but there is one matter that I think is overlooked, and requires more attention than appears at first view—and if not the base of Mr. Comstock's proposed system for his million of dollars, is and has been mine for years; and that is, how long a plant can be cultivated without injury to the growing crop, or at what stage of growth should we cease to work a plant to obtain its greatest yield.

I have heretofore given my views in regard to Indian corn, and I will now give some experiments made several years ago for my own satisfaction; but there has been no repetition of these experiments, as they fully corresponded with my views before making them. 1st. Two double rows (25 yards in length) of peas were planted, with an alley of three feet between the rows; they were all hoed when the pea-vine was about eight inches high, and at this time supports were placed to one of the rows. The other row was left without supports till the first blossoms made their appearance, when it was hoed again and then stuck. The pea-vine in the first row attained the height of about three feet six inches, and bore abundantly. The row hoed, when coming into bloom, attained the height of about twenty-eight inches, and the crop was not equal to one-fourth of the first row. 2d. Two double rows of bush beans were selected and treated with the hoe in like manner, but here the result was somewhat different; the hoed, when coming into bloom, were checked in growth; but in a few days new branches began to push forth, and upon these branches the beans were good, but on the first branches the pods were short and defective, and the crop not equal to the first row. The roots of some of these vines were carefully examined, but to speak of this part of the plant in this communication, would not only extend this article to a great length, but would be out of place, and I will conclude this exposition by saying that a similar effect was produced in the yield of the crop, upon two rows of potatoes treated in like manner.

Having laid by (to use a common phrase) a young peach orchard of over 600 trees, I may in due course of time have to recur to this subject again. Lyttleton Physick.

Ararat Farm, Md., June 28, 1843.

Albany Cultivator.

Tomato Sauce.—Take ripe tomatoes, cut them in two, press out the pulp and separate the seeds; then put them into a skillet with some savory sauce and a little salt. When of the thickness of pea soup, rub it thro' a coarse cloth, boil it to the consistence of marmalade, put it into jars, and in a day after it pour over it lard or butter, and tie down with oiled paper.

MANURING COTTON LAND.

The following we copy from the South Western Farmer, and we presume it is from the pen of M. W. Philips, Esq., one of its editors. It illustrates as strongly as a single experiment can, the incalculable benefits of manuring cotton lands. We commend it to our readers;

We feel disposed to give some description of the portion of our cotton crop that was manured this season; not believing the present appearance sufficient, to induce our brother farmers, to go into the manuring business, on the ground that there may be some peculiarity in the season that has made the crop more favorable, or the manured portion may not even yet give such a yield as the residue.

We hold one thing proper in farming, no experiment should be considered valid until tried three years at least, and then the exact returns should be given; though there can be no exception taken to one who gives his opinion *from present experience*, thereby putting one on his guard, as much as selling property and refusing to warrant soundness.

On giving this part of our crop its last plowing on the 8th of July, it was done at some injury, from the unavoidably breaking of some of the limbs that had in many portions of it met across the rows. There are portions of the field, of the same row, frequently at a less distance than 6 feet, that one stalk has not as many bolls or forms as a limb has on its neighbor, where manure had not been applied. On a very poor piece, where what little soil ever was has been gone for ten years, the cotton will show with any on the place; and yet portions of it, where the manure was accidentally not spread, is now not over a foot or a foot and a half high: a half dozen large bolls would quite break down the plant. In other words, where the manure was sufficient, the crop promises for a rate of 15 to 20 hundred weight, and within 10 feet, the crop planted same hour, and worked always the identical time and manner of the other, will not, cannot, produce 500 lbs. per acre. We have shown it to a number of persons, who have favored us with their company. They agree that appearances speak in the loudest manner in favor of manure.

Our object in speaking of it at the present time is, that all who have such land, can commence so soon as their present crop is off hand, to prepare manure, and that they may come and judge for themselves. When we used the manure on our land, it was prior to the appearance of Dr. Cloud's article, and was done to improve the piece of land (24 acres) that we design for an orchard, though fully believing the gain of the crop would amply reimburse. Not prepared for so great a difference, we did not give room enough; nor having a present return so much at heart, we did not use care in scattering the manure.

We have a small portion of this same field, that was manured in '40, '41 and '42—and no portion of it but what shows a marked improvement. A and friend myself counted on the 15th of July, 12 distinct forms and bolls on one limb, on the land where manured in '41—whereas on an adjoining row, we entertain no doubt 15 to 20 was not on a plant.

We have even now been preparing for manure, and would be happy, if we could know that our neighbors every where had buried enough grass to "do likewise"—but fear cotton picking will catch some of them burying the thing. Take warning friends, and the next year buy two horse-plows, and good single plows; though they may be heavy and require hard work. Yet you will gain *sometimes* a month's work in July and August, besides having your crops in good order earlier. We anticipate not to run a plow after the 19th or 20th —though we would if we could, not to injure the cotton—by breaking it.

We give this not as any thing new, and only to awaken attention to the matter; were we to advise, we would say use manure in abundance to a corn crop; it is an essential one; follow this crop with cotton, having the corn stalks buried with a two-horse plow; this plan would give the cotton crop great advantage, and would ensure a bountiful crop of corn, which would feed more stock, make more manure, and thus enable you to give land its due—an occasional feeding.

THE IMPROVEMENT OF THE SOIL, &c.

We recollect when but a boy, seeing an old plantation on the Catawba river, containing some two or three hundred acres. It was then regarded as exhausted land, and consequently its fences were suffered to rot, or were burned, and for many years it lay out as forsaken. But at length it fell into other hands, and an effort was made to reclaim it. About one hundred acres were first enclosed, and with a large two horse plough it was thoroughly broken up, early in the fall, turning under all the vegetable matter while green. In this condition it lay until about the first of February, when it was again well broken up, with the same big plough, after which it was prepared and planted in corn for one year, and produced probably as fine a crop as most new land with the first crop. We believe there was very little, if any manure, put on this land the first year. After the corn crop was gathered, this field was sowed in small grain, and produced a very fair crop; when this came off, the land was broken up as at the first, and lay thro' the winter as before. What method has since been pursued with this land, we are not able to say. But after being in constant cultivation now, for fifteen years, when we last saw it, about eighteen months since, it still produced equal to the best Catawba lands. All the old fields belonging to the plantation had long since been brought under the same treatment, with the same success; and some two years ago, this same land, which when a boy we were taught to regard as worthless, sold for $20 per acre, thus showing what may be done with proper skill, combined with persevering industry. In this instance our heart was made glad to see the noble forest, still standing almost entire, in the neighborhood of these once old fields, that were now "covered with the smiling corn."

Much has been said against "book farming," and we very well know that book knowledge will not make corn grow, but we also know that agricultural knowledge, united with agricultural industry and perseverance, will, as it has done in many cases, convert the barren desert into a fruitful field; while industry without skill, will certainly convert the most fruitful field into a barren waste, as we have seen in hundreds of instances over the upper part of our fair Carolinas and Georgia.

We suppose that old Virginia family, where that time honored rock has been kept from generation to generation, to be put in one end of the bag when they go to mill, are an industrious family, and yet we venture to say they have never converted an old worn-out, thrown-away field into a fruitful garden, smiling with an abundant harvest. They are still poor, hard-working, and we have no doubt, honest people. But why do they continue to use that old shaft plough? Why are their horses still fed in a manger outside of the gate, a hobble put on them, and they required to graze, exposed to the weather, where nothing is to be procured? Why, in a word, is that old rock still kept in that industrious family? We suspect they have never read the Southern Planter, published at Richmond, Va., nor any other Agricultural periodical. They are ignorant of the principles of Agriculture. They have not the knowledge requisite for tilling the ground to advantage, and therefore their toil is misapplied, consequently they are still poor, notwithstanding all their industry. It is not long since, we heard a man say of another, "what a difference betwixt that man and his father. I knew his father well, he was a very industrious mechanic, he worked hard, early and late, he understood his business well, that is, the mechanical part of it; he was also a sober man, and that man lived and died a poor man. But there is his son, following the same trade. He never seems to be in a hurry. You seldom see him work with his own hands, he always appears to be at his ease; and yet that young man has managed to acquire a large fortune in a few years." We asked what caused the difference. The answer was, "the one had industry without management, the other combines management with industry." We are proud to say that young mechanic is now one of the wealthiest, and most respectable men of the place. Let us apply this to tilling the soil, either as Planters or Farmers, and we will soon find the true reason why so many industrious, hard-working men, labor so hard on poor land to so little purpose,

It is an old, but very true saying, "knowledge is power," no matter to what branch of science or profession or business it is applied: and we hold that the power of knowledge is as important to the profession of Planting, as it is to Medicine, Law, or anything else. Would that the cultivators of the soil would lay this to heart, more than they do. But whence is the requisite knowledge to be derived? This, we confess, is a very important question, and our only answer is, from experience. Experience is said to be a good teacher in all things, and we would suppose it especially so in Agriculture. But the objection here is, "most of us have no time, no means to make experiments." Experience is generally a very dear and slow teacher. Then we would say, let us avail ourselves of the experiments of others, those of our own country and age, as well as of other countries and past ages. But to do this, we must read Agricultural papers. Very well: but this will cost us something! So it will—a few dollars a year; but if by that means you raise a better horse, cow, sheep or hog, at less expense, you will not lose by the operation. But then we have no time to read newspapers! To this we would say, it is more agreeable to devote an hour or two in the week to the perusal of an interesting newspaper than to do that much extra work in the field; and if the knowledge gained by one hour devoted to the paper, will save two hours of hard work in the hot sun or pinching cold, you will certainly be the gainer by it. We would therefore say, by all means take an Aricultural periodical.

But, as we have been led on by this subject, far beyond our original design, we will here close for the present.

S. C. Temperance Advocate.

TOMATO KETCHUP.—Bake your tomatoes ripe and peeled, in a brown earthen pan, in a cool oven; then press out the juice and pulp through a sieve. Next to each quart of juice and pulp add ½ lb. of salt, 2 oz. of shallots (or onions) 1 oz. of ground black pepper, ¼ of an oz. mace; the same weight of allspice, ginger and nutmeg. Pound the spices together and boil them with the tomato pulp half an hour; then pass the mixture through a sieve, and when cold bottle it. This will keep good for years.

TOMATO PICKLES.—Take tomatoes when two thirds ripe—prick them full of holes with a fork; then make a strong brine, boil and skim it.—When cool, put your tomatoes in: let them remain eight days, and then take out and put them in weak vinegar. Let them lay 24 hours; then take them out and lay a laying of tomatoes, then a thin laying of onions, with a teaspoonful each of cinnamon, cloves and pepper, and a tablespoonful of mustard; then pour on sharp vinegar. You may put them in jars, if you like.—*Michigan Far.*

How many hundreds of human beings in this world, have died in poverty and wretchedness, from the fact of their being taught that *labor* was *degrading?* Oh! what a shame, and still we see this idea taught in the 19th century.—*Ten. Agr.*

COMMUNICATIONS.

SEED.

Conalagga, Macon Co., Ala., August, 1843.

Seed is the deciduous part of a plant comprising the rudiments of a new plant. It is the new plant in its embryo state containing the germ of the future plant, and the parenchyma which nourishes the young plant until its roots seek nourishment in the soil. The ultimate object of the growth of plants is the perfection of seed; consequently, every thing which hinders or injures the perfect growth of the plant, must derogate from the perfection of the seed. This is as plain as that cause produces effect. As the seed is the rudiments of the new plant, of course the plant partakes of every imperfect quality of the seed, with which will be combined in the new seed further imperfections, the result of injuries sustained in its present growth. These combining in the lineal descent effect from every extraneous cause, every one have a tendency to lessen the perfect growth of the plant, and to hasten its degeneracy, which seems to be a natural consequence. Some seed mature well on any soil; others are more choice, and require their peculiar soil, to which they are adapted. Cold wet land is injurious to the perfection of any seed, before the soil becomes incorporated and its rankness neutralised, the seed does not mature well. This and many other varieties of soil produce results different in germinating seed; but to discourse these particulars, would protract this article to too great length—suffice it to say, that light mellow soil, to which the sun has access, produces the best seed cotton—it is well known to mature best on a sandy loam—corn and small grain on a clayey loam. Climate seems to be the parent of the genus of plants producing its peculiar kind, which may be reproduced in the same climate without diminution, but when produced in foreign climes, it must suffer either a change of kind degeneracy, or destruction. The incidents attending the growth of plants, which are injurious, and which detract from the purity of seed, are very much rain at a certain time, giving to the stalks too luxurious a growth, scatters and prevents the assimulation of the fecundating matter—noxious weeds and grass crowding near, drawing the nourishment from the soil, preventing the gradual and uniform extension of the roots—wounds of the stems or branches prevent the regular flow of the juices—cutting the roots when the plants commence to bear seed, curtails the resources of the plants and diminishes the supply of matter so essential in the ultimate purpose, the perfection of seed. To raise seed to perfection, or as near as may be allowed, we should have peculiar regard to the selection, choosing the heaviest and most perfect, plant them at a proper time, upon soil judiciously selected, nourish it well, give every help to its growth, top off its superfluous branches, remove every thing which would operate against its growth or healthiness, gather the seed when perfectly matured, which may be ascertained by the dryness of the stem, and put them away perfectly dry. I am aware that perfection is hardly attainable in any thing, for accidents will occur, though we strive assiduously against them. Yet, if we endeavor to carry out these principles, by applying judiciously all the means within our power, though accidents may occur tending to blast our efforts, their effect will be lost in the succession by its strong tendency to perfection, and an improvement will be attained upon the common stock, and a reward for our toils.

William Todd.

CULTURE OF COTTON.

Messrs. Gaylord & Tucker—I perceive from your last number that Dr. Cloud's plan of cultivating Cotton, or at least his statement of its results, is received generally with small favor and less faith. While those of "little faith" and perhaps of smaller works, are condemning his plan and discrediting his statement, it is but fair that those who have adopted similar modes of cultivation, with similar results, should give him and the public the benefit of their testimony.

In the months of January and February, in the year 1841, I had a lot of five acres opened at intervals of 3½ feet, with furrows down to, and sometimes into the clay. In these furrows I deposited stable manure at a rate not less than 400 bushels per acre. and running immediately upon each side of these furrows with a turn plow, I buried the manure. Thus my beds for cotton were partly made: the superincumbent soil prevented, at least in part, the escape of the volatile portion of my manure, which being put deep, and the soil gradually accumulating over it in the process of cultivation, it was kept at all times properly moist, without which it does but little good.

Cotton being a tap-rooted plant, I doubt not that it would be an improvement upon the above plan, to open with a coulter plow, the clay or subsoil in or rather under these furrows, before depositing the manure; to the end that the soluble portion of the manure might subside gradually to a still greater depth. The lot which I manured upon the above plan, was originally a thin soiled chestnut ridge; had been cleared between forty and fifty years, and was of course completely exhausted. Indeed 200 lbs. of seed cotton per acre, would have been considered a good crop for such land, upon the usual plan of cultivation without manure.—About the last of March, I put two additional furrows with a turn plow, which completed my beds. These beds I opened with a coulter, sowed the seed in the usual manner, and covered with a board. This lot, thus manured and planted, received no extra care in the after culture, was treated in every respect like the balance of my crop. The result was 4,430 lbs. of seed cotton from the lot, or 886 lbs. per acre. But as I sowed this lot in wheat in the fall of that year, and before the cotton had been all neatly gathered, I may fairly set down the yield of the lot at 4,500 lbs. or 900 lbs. per acre. Here was an increase of between four and five fold the first year, and as I have planted upon land similarly treated, and gathered a second crop equal to the first, I consider myself as yet in the midst of an experiment, the final result of which can alone determine the full amount of benefit to be derived from a single application of manure. It will be at once observed that my plan differs in several points from Dr. Cloud's. I drill at 3½ feet, and chop out in the usual way, leaving the stalks as nearly as possible from 18 inches to two feet apart: while he checks at three by five feet. Thus he gives to each plant an area of 15 square feet, while I do not give an average of 7. He spreads and plows in 300 bushels of manure per acre, broadcast, while I apply none in that way. His was a deep sandy soil, with clay at a depth of 2 or 3 feet; mine a very shallow, stiff, red soil, with a very firm red clay, lying at various depths, from 0 to 6 inches below the surface, with an abundance of white flint or quartz rock upon it. The 300 bushels of manure which he applied broadcast, was doubtless of great advantage to his crop, and would in all probability have doubled mine. In other respects, I think his plan the best for his land; and mine, with a little more space to each plant, the best for mine.

The incredulous will of course consider this experiment of mine as lending no countenance to Dr. Cloud's statement: but when every circumstance is fairly considered, I think it does. My experience, however, does not stop here. I cultivated the same year another small lot about 85 yards long and as many wide, or 7225 square yards, which is 1 477-968 acres, or rather less than an acre and a half. This lot, in its primitive state, was of precisely similar quality with the 5 acre lot. About one-third of an acre of this, certainly not more, had been for several years a stable lot; the balance of it, descending from this by a considerable declivity, I cultivated, believing it may have been benefitted by washings from the stable lot portion. The surface soil had been nearly all washed away for years. The manure upon the stable lot portion had been carefully scraped up and removed, so that the manure left was such only as had been absorbed by the soil. To the other portion no manure was applied. This lot was broken up deep and planted about the last of March, and the rows running horizontally around the declivity, were from 3 to 4 feet wide, accordingly as the land was considered poor or otherwise. From this lot I gathered 1,707 lbs. cotton in the seed. Of that I set down 1,400 lbs. to the stable lot portion, leaving to the balance 307 lbs, which I am sure is a liberal allowance. But little of the weed on this lot, except on the stable lot portion, attained a height of 18 inches—much of it not even 6 inches. The stable lot portion had attained an average height of 6 feet by the last of July, and was so much interlocked that it was impossible to pass through it without doing great injury to the branches. By the middle of August, the weed on this portion ceased growing and the whole vegetative energy of the plant seemed directed to the development and maturity of bolls, of which there were vast numbers. This cotton suffered much from two causes. It was too much crowded, which caused a very great number of the earlier or bottom bolls to rot for want of sun and air. Towards the latter part of August, a wet spell of weather of several weeks duration set in, which producing a second growth of the weed, caused vast numbers of furns, blooms, and young bolls to fall off, which a moderate season would have matured Under all these disadvantages, there was still a yield at the rate of 4,200 lbs. per acre.

I have only room to add that I highly approve of Dr. Cloud's plan, and that my own experience and observation forbid that I should discredit the general correctness of his statement. I have long been of opinion that it would be of great service to the cotton region of South Carolina and Georgia partiularly, to divert at least one-third of all the labor employed in raising manure. The result would be equal crops of cotton at least, upon a greatly reduced number of acres; the improvement and renovation of our worn lands; larger crops of corn and grain; more hogs, cattle, sheep, horses and mules raised at home—our country, in short, adorned, beautified and enriched.

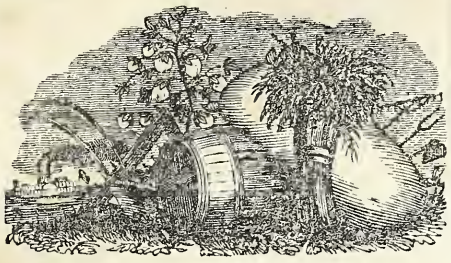
Very respectfully, yours,

S. Fouche.

Taliaferro Co., Ga., June 23, 1843.

Southern Cultivator.

Blackberry Syrup.—The following directions for preparing this article, pleasant for the taste, and the best remedy for the summer complaint among children, we find in the Maine Cultivator. To two quarts of the juice of blackberries, add one lb. of loaf sugar, half an ounce of nutmeg, half an ounce of cinnamon pulverized. To this add half an ounce of cloves, and quarter of an ounce of allspice, pulverized. Boil all together for a short time, and when cold, add a pint of proof brandy. Bottle carefully, and keep in a cool place for use.



WEDNESDAY, SEPTEMBER 13, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

THE CROPS.

The prospect of the corn crop is indeed most flattering, from every section of the Union from which we have any intelligence, and leads to the conclusion, that the crop will be very abundant. Of our own great staple, however, the prospect is not so cheering to the heart of the husbandman. Although it may be justly regarded too early to speculate with any degree of certainty as to the growing crop of cotton, yet all concur in the the opinion, that the late spring, and the continued rains of July and August, which were general throughout the cotton growing region, have operated so prejudicially, that the most favorable fall ever known could not produce as large a crop as that of last year. Nor is this in our opinion desirable, yet we should be pleased to see a fair average crop, which we think will be produced, if the frost keeps off till the 15th of October—provided the weather continues favorable for the maturing of the staple till that period.

WILKES COUNTY AGRICULTURAL SOCIETY.

In the Washington News we find the following notice of the proceedings of this Society, at a meeting held on the 7th inst. We also learn from the News, that the amount of the premiums to be awarded by the Society, will be regulated by the state of the treasury at the time.

Resolved, That premiums be awarded for the following stock, to be exhibited on Friday, the 20th of October next, in Washington:

For the best Horse.
" Colt, under one year old.
" Cow.
" Native Cow, which if she be the best cow exhibited, may take both premiums.
" Bull.
" Boar.
" Sow.

It was further *Resolved*, That none shall compete for the premiums who have not become members by paying the admission fee of one dollar, and signing the constitution; though all persons are invited to attend and exhibit their stock.

The semi-annual meeting of the Society will take place on Friday, the 20th of October, at which time a public address will be delivered by a member of the Society.

It has been our purpose, and our constant effort, since our attempt to establish an agricultural paper at the South worthy of the patronage of Southern planters, to render it the fit and proper medium of communication for whatever pertains to the progress of agriculture around us. We have therefore felt some surprise that the officers of the few Agricultural Societies in Georgia, should seem studiously to avoid giving to us, directly, any information connected with their respective societies, their progress, &c. &c. In the absence of which, we have been compelled to glean whatever of their proceedings we have from time to time published, from our exchange papers—papers not devoted as ours, exclusively to the cause of Agriculture. We mention this fact in no spirit of complaint, but simply to notify the officers of the respective societies, that we deem our paper the appropriate medium for communicating their proceedings to their brother planters, and shall always take pleasure in giving them a place, together with any interesting or valuable facts they may feel disposed to communicate. It is true, every Society has an undoubted right to give its proceedings publicity through whatever medium it may choose, or deem most fit and proper—a right which we shall not controvert, or of the exercise of which complain. Yet at the same time, we feel that something is due to us from those in whose behalf we are devoting our energies, and while we express a willingness to give place to such items of intelligence, the withholding of them by the officers certainly savors of a disposition not to second us in our efforts. We therefore hope that the Agricultural Societies throughout the State, as well as those in South Carolina and Alabama, who may feel disposed, will in future avail themselves of our columns as the proper medium through which to give their proceedings publicity.

GAPES IN CHICKENS.

The following is an extract of a letter received from a friend in Caroline:

"It writing to you, it will probably not be amiss to communicate a fact which will be of some interest to *the lovers of fried chickens.*—Some of my neighbors have entirely prevented, and others have speedily cured that destructive malady, the gapes in their chickens, by mixing a small quantity of spirits of turpentine in their food. From five to ten drops, added to a pint of meal to be made into dough, are the proportions used. I have no doubt of the universal and certain success of the remedy, relying, as I do, upon the character of those who have communicated it to me. Yours,

BENJAMIN ANDERSON.
Southern Planter.

NEATNESS.—"A place for everything, and everything in its place." This should be the motto of the farmer. Neatness, of all virtues, is the most commendable, for without it no other virtue can long exist. Supposing a farmer has a slatternly wife—can he, think you, be as good a husband as though his helpmate was neat and tidy? Assuredly not. There will be so many crosses—so much of provocation and annoyance, and so little of uniformity and system in her domestic arrangement, that he will sometimes find fault, and vent the fullness of a just indignation in censure "loud and deep." This is always unpleasant—always disagreeable, what every one whose "combativeness" is not the ruling passion, the predominating characteristic of his mind, will by all means labor to avoid. On the other hand, a slack, indolent husband—given to much smoking, horse-racing or tavern-haunting, will destroy the felicity, and break down the energies of the best wife in the land. There is nothing, perhaps, of which woman-kind are more invincibly tenacious, than of their domestic emolument; those little rights and privileges which pertain exclusively to the "realm within;" and whenever these are wantonly invaded—no matter whether by an act of sheer indolence on the part of the offender, or by brutal aggressions arising from a vain and capricious spirit of causeless interference, the harmony of the "marriage state" vibrates into discord, and the whole machine is at once thrown out of gear. A quid of tobacco in the batter pan, or a pipe full of ashes in the stew-dish, is enough to destroy the equanimity of any woman; while dishes never washed, beds never made, and floors never clean—with all the other innumerable and unmentionable negligencies which add to the repulsive catalogue of a slut's offences, are sufficient to upset the equanimity of a stoic, and unhinge the patience of Job himself. To a person thus circumstanced,

"There is 'na luck about the house."

No matter how prosperously the world may go without, all within will be strife and discord, and the "latter end of such, ten to one, will be more wretched than the first."—*Maine Cul.*

WORK FOR SEPTEMBER.

As much of the success of next year's labors will depend upon the manner in which the work of *this month* may be executed, we feel that we cannot too urgently impress upon our agricultural brethren the necessity of paying particular attention to every duty now devolving upon them, and to see that whatever may be done, shall be performed in the best possible manner, and that no *delay* which can be avoided be permitted to take place as to the *time* of its performance. With this brief introduction, we shall proceed to point out what ought now to be attended to

ON THE FARM.

Fall Ploughing for Grain.—Many of you have doubtless commenced this work. To such we say, push on with your labors until you shall have completed them. To those who have not begun, our advice is, to begin without another day's delay; and on both we would urge the propriety of observing care as to the manner of ploughing. Let your furrows be ploughed deep, and the slices so laid as to bury all vegetable matter and pulverize the soil; for, believe us, these are objects of the very first importance.

Seeding Rye.—In putting in this crop *see* that you commit your seed to soil calculated to remunerate you for your labor, as it is fruitless to be expending your force and time on land too poor to yield a compensating return. Where the ground may be *really* poor, by the application of a bushel of plaster and two bushels of salt, or four of ashes per acre, you may place the soil in a position to make moderate amends for its lack of fertility, as these substances will absorb nutriment from the atmosphere, assimilate with it, and dispense it to the crop, as well as maintain a healthful moisture throughout the season. Be sure, too, to get your Rye in early, and to sow at least five pecks to the acre. It is scarcely necessary for us to remind you, that no land should be seeded before it is finely pulverized by repeated harrowings, and that after the seed is in, it should be again harrowed and finished by rolling.

Seeding Wheat.—We last month endeavored to impress upon you the propriety of *early* seeding, and we will here repeat, that we believe much danger may be avoided by getting in this grain much earlier than you have been in the habit of sowing it. We will sum up our advice in a few brief rules: *Sow early—sow plenty of seed, not less than two bushels to the acre—soak your seed in salt brine or ley, for* 12 *or* 24 *hours before sowing, and as you take it out to sow, dry it in lime or ashes—if your land has not been limed or marled, sow thereon five bushels of lime per acre, after the seed is in—if your land is not rich, sow over each acre a bushel of plaster and two of salt.* Indeed, whether rich or not, we think you will find your interest promoted by sowing the plaster and salt over it, as we believe it would have the tendency of not only fixing the ammonia in the soil, but of retaining it in store, to be fed

out *gradually* to the growing plants, and of pr? venting to a certain extent, the rust.

Sowing of Grass Seeds.—All meadows intended to be set in grass seed, should be prepared and sown as soon in this month as possible. The soil should be made fine and plenty of seed be sown. The following proportions will anwer:

If Timothy alone, from 1 to 1½ peck per acre, the latter quantity the most eligible one.

If Orchard grass alone, 2 bushels per acre.

If Red Top alone, 1 bushel per acre.

If a mixture of any two of these be desirable, one half the quantity of each should be sown.

The following mixture would make a good one: 1 bushel of Rye grass and one of Orchard grass, to be sown early in this month, and to have 12 lbs. of clover seed per acre sown thereon next spring as soon as the seed can be lightly harrowed in and rolled without injury to the ground.

Recollect that a *light harrow* is better than a bush harrow, as the latter always drags the seed into irregular masses.

Draining and Ditching.—This month is advantageously suited to such work, and if you have any arable ground that is *wet*, be sure to have it drained, as no plants can thrive as they ought to do in a wet bed.

Weeds, Leaves and Mould.—Can we prevail upon you to go to work with one of your teams and a hand or two, and collect some hundreds of loads of these substances and cover over the yard in which you intend to keep your stock. By doing so now, they will become consolidated by the time you yard your cattle; and rely upon it, that they will make every pound of it good manure by next spring; but if you desire that there shall be no loss from evaporation of the *gem-like liquid*, spread a bushel of plaster or charcoal over the mass, once in two weeks, from the time you yard your stock until you cart out your manure in the spring. Be sure, too, in forming your yard, to make it in the shape of a basin, so that none of the rich fertilizing juices may be washed away.

Hogs and Hog Pens.—If you have the means of pen-feeding, pen some of your hogs, and provide them with materials to convert into manure for you.

Salting Stock.—Take equal parts of salt and lime, mix them together, and give to every animal on your place, twice a week, one gill of the mixture.—*American Farmer.*

MIXTURE OF SOILS—SAVING OF URINE.

The improvement of our lands, by the mixture of soils, is a means almost entirely neglected in our country. There have been, to be sure, a few honorable and striking exceptions; but these are so few as to be scarcely worthy of notice; for their example appears to have been unproductive of a tithe of the influence to which they were intrinsically entitled. In England, however, instances are as numerous as they have proved beneficial, where the most striking and lasting improvements have been brought about by simply mixing clay with sand, and sand with clay. By this process, not only the *textures* of the soils of extensive landed estates have been changed, but a capacity for retaining the benefits of manure imparted to loose sands, on the one hand, while on the other, stiff unwieldy clays have been so broken down in their adhesiveness, as to be rendered friable. Nor is this mechanical change, so beneficial to either grade of soils, the only resulting good. As in all virgin clays there are a greater or less proportion of potash, and more or less portions of lime and the other mineral salts; so that by adding and mingling such clays with loose sands, we not only convert them into moulds, but supply also, many of those salts which are absolutely essential to healthy and productive vegetation.

The above reflections, as to the advantage of using clay as an auxiliary manure for light sandy land bring us to the consideration of the question, as to the best and cheapest method of applying them. In a country like ours, where labor is dear, and time may very properly be said to be money, there are but few of us who could probably undertake to give at one dressing the requisite quantity of clay, to convert, by admixture, the sandy into a loamy soil; but the end can be attained in a way so that neither the labor nor the expense will be materially felt as a tax. Let a hundred or two loads of clay be, at the beginning of every autumn, spread over the barn or cow yard, and thereon be placed a covering of leaves and mould from the woods. Such a body of materials would comprise an admirable bed for the cattle to winter upon—would form an absorbing substance to drink up and retain the liquid voidings of the cattle thro' the fall, winter and early spring, which when mixed, at the time of carrying out the manure, with the litter and solid excrements which had in the the interval accumulated thereon, would prove a body of manure rich in all the elements of fertilization, as well as form a basis for *amending* the soil of singular value. By repeating this course of applying the clay, a vast amount of liquid manure would be saved that is now lost, and the texture of the soil would be changed in a few years, without the time or expense being seriously felt. But to render the value of the *liquid* manure the more available, or in other words, to prevent the loss of its more valuable and volatile parts, it would be well to spread a few bushels of plaster and or charcoal over the clay, say 1 bushel to every 20 loads, so proportioning its distribution, as to have about one fifth part spread every three or four weeks. By this means there would always be a fresh body of plas er or charcoal present, to assimilate with and prevent the escape of the ammonia of the urine of the cattle, and thus preserve it for the purposes of fertilization.

Without entering into any minute calculations upon the subject, it may be assumed as the result of chemical analyses and experiments, that every animal of the cow kind kept in a barn yard, when well fed voids urine enough each day, if the escape of the ammonia were prevented, to manure ground enough to produce from two and a half to three pounds of wheat—this is less than the quantity claimed—and that three-fourths of that gas can be saved by the judicious use of plaster or charcoal, in the process we recommend, we do not hesitate to state as our honest belief. If such be the state of the facts in the case, every farmer can make his calculations as to the loss he annually sustains, by letting the urine of his cattle go to waste, and if he be prudent, he will not hesitate as to what is the proper policy for him to pursue.

We have referred to this subject at this particular time in order that farmers may be reminded of it in time to make the necessary arrangements against fall, to avail themselves of the advantages to result from such a husbanding of one of the very best manures that they can use. In speaking of the several substances, we have endeavored to be plain, in order that, in striving to be useful, we might not run the risk of bewildering.—*American Farmer.*

Industry and frugality, is the surest road to ¡ndependence.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, Jr.,
No. 232 Broad street, Augusta, Ga.
August 30. 18–tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18–tf WM. HAINES, Jr.

BOMMER'S PATENT MANURE.

THE undersigned is the Agent of Messrs. Abbett & Co., for vending rights to individuals for making and using the above named Manure. By reference to the following advertisement of Messrs. Abbett & Co., the prices may be ascertained. All orders addressed to me, *post paid*, at Sparta, Ga., will receive prompt attention.
Aug. 30. 18–tf R. S. HARDWICK.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days.* And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent $6
Farms up to 100 acres 10
" from 100 to 200 acres 15
" " 200 to 300 " 18
" " 300 to 400 " 20
" over 400 acres in any one farm 25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.
ABBETT & CO., Baltimore,
Proprietors of the patent right for the Southern and Western States. aug 16

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., SEPTEMBER 27, 1843. No. 20.

Having published the article from the Albany "Cultivator" to which the following is a reply, it is perhaps but justice to our readers that we should give them the reply, in order that they may avail themselves of all the lights that may be brought to bear upon a subject of such high import to the planter.

—

From the American Agriculturist.

IMPROVEMENT OF DOMESTIC STOCK.

Under this head, we find in the Albany Cultivator for last month, a long and elaborate article, parts of which recommend a course of breeding so directly opposite to all true principles of which we have ever read, or heard, or seen practised, by anything like what we should consider authority in this matter, that we cannot pass it over in silence; for, if acted upon, it would totally destroy, in a single generation, every choice breed of animals that we now possess, and which it has cost this and other countries, so much time, labor, and money, to bring to their present state of perfection. The Cultivator says, page 107, July No.:—

"But it may be doubted by some, whether any improvement on the best of the present high-bred cattle, is possible, and the idea of it be scouted as an absurdity. 'What,' it may be said, 'talk of improving a breed by crossing them with those still lower in the scale?' *We answer yes, and hope to shew there is nothing chimerical in the plan.* For illustration, we will again recur to the Short-Horns, as unquestionably at the head of the improved breeds. Breeders have enumerated a great number of points as going to make a perfect animal; to make one absolutely perfect, we will suppose that 30 enumerated qualifications are requisite; that the Short-Horns, as approaching the nearest to this standard, possess 20 of the desired qualities; and the other varieties or breeds in a descending ratio down to our native stock, which may be put as possessing but 5 of these requisites. The question is, can an animal possessing 20 good points be improved by one possessing only 10 or 5? We answer yes, if the one possessing 20 is deficient in any of the points possessed by the lowest, or by 5. 20 may be deficient in hardihood or the power of enduring our seasons; in milking properties; adaptation to labor; quality of flesh; or some other point or points possessed in a remarkable degree by 5; and this deficiency remedied by a skilful cross with 5, which shall engraft and fix the valuable point on 20, would make it 21, or furnish a decided advance towards animal perfection."

Now the idea of improving an animal that has twenty good points, with one that has only five, we cannot characterise by milder terms than saying, is as gross and perfect a piece of absurdity as we ever heard. The Cultivator seems to suppose, that man has the same plastic power over the animal creation, that the sculptor has over his clay model, and that wherever there is a deficiency in his subject, he has only to supply it with additional mortar, which he takes up from his heap at pleasure, or where there is an excess, to simply pare it away! Now the only true principle of improvement in breeding which we ever heard of, is this: If an animal be deficient in any one point or more, it must be crossed by another animal *equal* to it in all its *good* points, and *superior* to it in its *deficient* ones; and then the chance barely is, that one half the produce may be *equal* to the *superior* animal thus used in the cross, and the other half not *inferior* to the *poorest*. But if an animal of twenty good points be crossed with one of only five, no experienced person would expect that the produce would possess over ten or twelve good points at most; and it would be a sort of miracle, if a single one of the produce had twenty-one good points infused into it. When animals are crossed, it is a law of nature that the blood mingles—it does not go in lumps. We must consequently take the bad with the good, and the extra hazard of deterioration, to which all breeds are constantly subject. We know that now and then, though very rarely, for example, breeding a superior Short-Horn bull to a native cow, and that produce, if a female, to the same bull again, that the third generation, the three-quarter bred animal, will sometimes be a very good one—to all appearance, nearly as good as the thorough-bred bull; but the produce of that three-fourths bred *cannot be depended upon* for equal and exact breeding. We have seen cows that had only one two hundred and fifty-sixth part of native blood in them, (and very fine animals they were too, individually,) bred to a choice bull, throw a calf occasionally very inferior, more resembling the dung-hill than the thorough-bred.

We suppose, upon this principle, that to improve the Spanish fine-woolled sheep in hardiness, (though we contend that the old-fashioned Merinos were as hardy as anything that stands on four legs,) the Cultivator would take a cross upon the old native, or other coarse-woolled breeds, thinking it could do so at will, without deteriorating the fine wool of the Spaniard. If so, let it look to Lord Western's experiments on this matter to be convinced of the ill-success of such undertakings. Again, to give size and strength to the racer, it would take a cross with the cart-horse, the most contemptible mongrels upon which we ever looked. We should be very glad to know *where* such animals would be *placed* after a thorough training, and a fast turn of a few miles on the course. We do not mean any unfairness in our argument by taking the cross of two different kinds for an illustration, but to place the subject in a stronger point of view, the ass is longer-lived than the horse; now suppose we wish to increase the age of the latter, why then we should breed them together, expecting that we should get, to a moral certainty, this *one* good point in addition in the produce, without any deteriorating quality of the ass. But does the mule show this perfection? And if it could be bred to the horse again, and its produce on till finally a thousandth part of the blood of the ass only appeared in the progeny, would not the shadow of its long ears still be seen, and the falsetto of its unearthly bray occasionally be heard? How is it with the cross of the Caucassian and Negro races? Divine authority has asked, "Can the Ethiopian change his skin, or the leopard his spots?"

Yet enough, for it would seem that the Cultivator is not a convert even to its own bold assertions, for further on it says: "But there must be no breeding *downward;* every cross must be *upward* both in blood and desired qualities."

There are some other positions that the Cultivator takes in this article, which are denied. For example: "It is rare indeed, perhaps never, that any single point is found in the highest degree of excellence, except at the *expense of some other point.*" We doubt, from the sentences which immediately follow this just quoted, whether the Cultivator understands what it is talking about.

We have not usually found, in our experience, "the deepest and best milkers of the herd the most raw-boned, not to say the worst-looking of the whole," but quite the contrary in well-bred Short-Horns. Did the Earl of Leicester improve the good milking qualities of the Devons at the expense of their fineness of points? Were the Ayrshires so improved? And are they attempting the same with the Herefords?

It is denied that Charles and Robert Colling were the originators of the Short-Horns; on the contrary, any reasonable amount of evidence can be produced in England, to prove that Chas. Colling repeatedly said, he never bred anything equal to the Short-Horn cow, which he purchased of the agent of the Duke of Northumberland. Where is the Cultivator's authority for its assertion? We suppose we shall be told of Countess that sold for 400 guineas—the Galloway cross, and all that sort of thing. Well, we shall be glad to have our memories refreshed with the story, and when it is repeated in full, we shall see how much it will avail the Cultivator.

Did "Berry and Coates co-operate most effectually in forwarding the improvement commenced by them," [the Collings]? This assertion is really too rich, and we would fain ask for the authority on which it is made. The Cultivator adds, that the reputation of being good milkers, "does not belong to the improved breed." Short-Horns, we suppose, it means. If it does not, we should be very glad to know then to what breed of cows it does belong. But this, we opine, would depend very much how they had been "improved." If by a cross with a scrub of five points, on a Short-Horn of twenty points, why then we have nothing more to say. We *knock under* to all such "*improvements.*"

The public will hereafter look to the Cultivator for a new era in cattle-breeding, and they may hope, some half century hence, by its new code of rules of "improvement," to get a decent milker or two! If the Short-Horn breeders put up with such gross calumnies upon their stock, why then we are greatly mistaken in their spirit, and the sooner their herds are driven back to the place from which they came, the better. We did really believe that some *few examples* had been given on this point, and that they had invariably offered to meet the breeders of native, or any other stock, to milk with them—cow for cow, or herd for herd, however small or large the numbers might be. But since the Cultivator asserts the contrary, why we suppose we must fain believe it. But here we have another question to ask. Is the Cultivator sure that the cows mentioned in its May No., by Mr. Heslip, as giving so great a product of butter and cheese, are *pure* natives? We know that Shorn-Horn bulls have been taken into Trumbull county, Ohio, and it is our firm belief that many of the animals there are grade Durhams in some way. We shall take the trouble, if possible, to get at the facts in this case. But native or not, we think that the breeders of thorough-bred Short-Horns will have no fear of matching their ani-

mals against them in the production of butter and cheese, grass and hay-fed, or kept in any other manner it pleases. For twenty-five cows to produce 13,715 lbs. of cheese, and 309 lbs. of butter, 548 lbs. each of the former, and 12 lbs. of the latter, we do not think so very extraordinary. We have heard of a cow making 21 lbs. of butter per week, and it was thought, with how much reason we do not know, that she might make 500 lbs. in the course of a year. What amount of cheese this would be equivalent to, we could not say, as this would depend a good deal upon the amount of caseine in the milk.

There are some other assertions in this article of the Cultivator, also a few paragraphs which have appeared from time to time in its pages, upon which we would like to offer a few comments, but our space forbids. We shall probably recur to them hereafter, as it seems to have an especial fondness for communication of this nature.

GREEN MANURING—OR THE APPLICATION OF VEGETABLE MATTER IN THE GREEN STATE.

JOHNSTON, in his lectures on the applications of Chemistry and Geology, has a very long and able article on the above subject, but as it is too long for insertion entire, we shall endeavor to give the practical results to which the writer arrives, from which the reader will be able to draw such conclusions as cannot fail to be profitable to him, provided he acts up to the advice which those results would impress upon his mind. These results are:

1. That the ploughing in of green vegetables on the spot where they have grown, may be followed as a method of manuring and enriching all land, where other manures are less abundant. Growing plants bring up from beneath, as far as their roots extend, those substances which are useful to vegetation—and retain them in their leaves and stems. By ploughing in the whole plant, we restore to the surface what had previously sunk to a greater or less depth, and thus make it more fertile than before the green crop was sown.

2. This manuring is performed with the least loss by the use of vegetables in the green state. By allowing them to decay in the open air, there is a loss of both organic and inorganic matter—if they be converted into fermented (farmyard) manure, there is also a large loss; and the same is the case, if they are employed in feeding stock, with a view of their conversion into manure. *In no other form can the same crop convey to the soil an equal amount of enriching matter as in that of green leaves and stems.* Where the *first* object, therefore, in the farmer's practice, is, so to use his crops as to enrich his land—he will soonest effect it by ploughing them in in the green state.

3. Another important result is, that the beneficial action is almost immediate. Green vegetables decompose rapidly, and thus the first crop which follows a green manuring is benefited and increased by it. But partly for this reason, also, the green manuring—of grain cropped land—if aided by no other manure, must generally be repeated every second year.

4. It is said that grain crops, which succeed a green manuring, are never laid—and that the produce in grain is greater in proportion to the straw, than when manured with fermented dung.

5. But it is deserving of separate consideration, that green manuring is especially adapted for improving and enriching soils which are poor in vegetable matter. The principles which *living plants draw a part—sometimes a large part—of their sustenance from the air, must be admitted, and add to their value as fertilizers.* Living plants, then, contain in their substance not only all they have drawn up from the soil, but also a great part of what they have drawn from the air. Plough in these living plants, and you necessarily add to the soil more than was taken from it—in other words, you make it rich in *organic* matter. Repeat the process with a second crop, and it becomes richer still—and it would be difficult to define the limit beyond which the process could be no further carried. Is there any soil which is beyond the reach of this improving process. Those only are so on which plants refuse to grow at all, or on which they grow so languidly as to extract from the air no more than is restored to it again by the natural decay of the organic matter which the soils already contain.

But for those plants which grow naturally upon the soil, agricultural skill may substitute others, which will increase more rapidly and produce a larger quantity of green leaves and stems, for the purpose of being buried in the soil. Hence, the selection of particular crops for the purpose of giving manuring—those are obviously the fittest, which, in the given soil and climate, *grow most rapidly, or which produce the largest quantities of vegetable matter in the shortest time and at the smallest cost.*

The plants enumerated by Professor Johnston, as best adapted to the purposes of green manuring, are: 1. *Spurry;* 2. *Pulse;* 3. *The Vetch;* 4. *Buckwheat;* 5. *Rape;* 6. *Rye;* 7. *Turnips;* 8. *Borage;* 9. *Red Clover;* 10. *Old Grass Swards.*

We have for years endeavored to impress upon such of our readers as had not the means of obtaining a sufficient quantity of animal and vegetable manures from their stock to manure their fields, how important it was that they should plough in *green crops*, and we are the more pleased to find that our views, so often advanced, are so ably sustained by the opinions and experience of so distinguished a man as professor Johnston. We have heretofore recommended that Buckwheat should be sown for the purpose of being ploughed in whenever lands were poor and its owner had not manure at hand to improve it. We recommended buckwheat because of the quickness of its growth, and the largeness of its leaf enabling it to appropriate to itself a very considerable portion of those nutritive gases which abound in the air, and form large portions of the food of plants.

We defer to no man in our estimate of the great value—the paramount importance—of *lime* to every soil calculated to produce vegetables; but still we have always thought that all soils require, besides mineral substances, those of vegetable and animal matter also, to make them partake of the highest elements of fertilization. We would not be understood as supposing that one crop of buckwheat turned in would be equal to a full dressing of rich stable or barnyard manure—but we do maintain that two crops turned in just as the plant comes into flower, would be equal to a very heavy dressing of any putrescent manure which could be applied. And upon the score of *cheapness*, we know of none where the party has to buy, that can compare with it; and then, when properly and evenly sown, *green manure* has this advantage, from the equal distribution of the vegetable matter over the entire field, there is an equality of fertility in all its parts, a thing most desirable, as every practical farmer will readily admit.

In conclusion, let us most respectfully advise all who may have exhausted lands and who may not have the means of procuring a supply of other putrescent matters, to make arrangements to sow and plough in a crop or two of buckwheat. Should they use lime or ashes in connection with the green-*ley*, so much the better—the more prompt and decided will be its efficacy. *Man requires bread as well as meat, and the earth requires vegetable as well as mineral substances.*

American Farmer.

Any deviation from the most exact and scrupulous sincerity, is repugnant to the good faith that ought to prevail in contracts. Any dissimulation concerning the subject matter of the contract, and *what the opposite party has an interest in knowing*, is contrary to that good faith.—*Pothier.*

It is not sufficient that we avoid what is wrong—we should also practice what is right. The former is a negative virtue, the latter positive.

NEW METHOD OF MAKING MANURES.

The subject of increasing their store of manures, is wisely occupying much of the attention of the farmers, for they find them indispensable in an improved system of agriculture. The greater the quantity, therefore, that can be made and judiciously applied upon their lands, the more certain their success in obtaining good crops, and adding to the profits of their business. The following extract is taken from the Farmer's Mine of Wealth, or Manure and Tillage; a very valuable work by Mr. Hermance, just published by Saxton & Miles. It gives a somewhat novel method of making manure; and by strictly following it, the farmer will find that he can greatly increase his resources, and work up into fertilizing matter what has hitherto been considered mere rubbish, and greatly in his way. For full particulars, and the benefits of this process, we must refer to the work itself.—*American Agriculturalist.*

1. Form your barn-yard with a gradual descent to one side, so that the liquid formed by the rains will flow gently to that side. Make the bottom as hard and smooth as possible, that there may be little or no waste by soaking into the earth. Arrange your stables, hog-pen, &c., in such order, as to throw all the litter and manure into the yard.

2. Sink a vat or reservoir at the lower side of the yard, of sufficient capacity to contain the juice of the yard. The most common form of the vat is six feet width by three feet depth, and twelve feet or more in length, according to the size of the yard, and the amount of liquor flowing from it. When the vat is more than twelve feet in length, it will be best to divide it by partitions into two or three parts, so that if at any time you want to use only part of the liquor, you can do so without any inconvenience. It will be farther desirable to have the vat so connected with the yard, that when once full, and you have commenced your manufacture, if additional rains come before you shall have completed your heap, of which we shall soon speak, you can prevent the liquid so formed from running into your vat, either by keeping it back in the yard, or by turning it in another direction.

3. In this vat mix the following ingredients as nearly as you can, without actual measurement or weight:—To every barrel of liquid, add 4 lbs. of stone lime just slacked, 4 lbs. wood ashes of good quality and dry, or an equivalent of leached ashes, or a ¼ lb. of potash; ¼ lb. of salt, or its equivalent of old brine; 2 oz. of saltpetre; 20 lbs. plaster of Paris, or mud, or muck; 10 lbs. of excrements from the privy, or 20 lbs. of horse manure. Mix these ingredients thoroughly with the liquid in the vat, and if the vat contains one hundred barrels, increase the above ingredients a hundred fold. It will be well to mix these ingredients a few days before you lay your heap, and stir them every day, but this is not essential.

On the upper side of the vat lay the foundation for the heap, by placing poles or rails, with one end to the vat, and the other extending from it, about two feet apart; on these lay other poles crosswise, precisely as we do the foundation for a stack of hay or grain) to keep the straw from the ground, and that the liquid may flow freely beneath.

5. Having every thing prepared, commence laying up the heap by placing a layer of straw, weeds, stalks, or whatever you have at hand, on the foundation of poles, to the thickness of a foot. You will find great advantage from throwing the materials as you collect them, in the yard, and letting the cattle tread on them, until they are thoroughly broken and wet. When the layer is a foot thick, stir up the ingredients in the vat, and with a pail or other vessel thoroughly wet the layer on the poles. Place another layer on the first, and of the same thickness, wet as before, and thus continue until you have raised the heap as high as you wish—say from six to ten feet. Be careful at every wetting to stir up the ingredients from the bottom of the vat. The easiest and quickest way to wet the several

layers, will be to use a pump or elevater, with a hose attached, to spread the liquor over the heap. In such case, let one stir, another pump, and a third manage the hose. Only be careful whatever method you pursue, to wet the several layers thoroughly in all their parts. When finished, cover the heap with the settlings in the bottom of the vat, or with any thing else at hand—common earth will answer.

6. If the heap consists of straw, weeds, and the like, it will require wetting every fourth day. If you have used much peat, muck, or earth, with the straw, water once a week. To water the heap, make holes with an iron bar or other instrument in the top of it, from eight to twelve inches apart, and extending downward about to the middle; then stir the liquid in the vat, and pour it in the holes until the whole mass is saturated; finally, close the holes. At every watering make new holes.

Give the heap three waterings when made of straw, and it will be fit for use in 15 days from the time of laying it up; when much mud or muck has been added, thirty days.

When it is desired to manufacture this kind of manure in places where barn-yard liquid can not be readily obtained, river, spring, or pond water will answer the same purpose for wetting the heaps as the barn-yard liquid, by increasing in a small proportion the ingredients for the mixture, as given in section 3, and adding them to it.

Bommer's Manure.—The agent of Mr. Bommer was here a few days ago, and had a heap constructed in Mr. Russell's vegetable garden. The materials are now rotted, and Mr. Russell invites planters who may feel any curiosity on the subject, to call and examine for themselves.

We expressed the fear some weeks ago, that the process would create a stench so offensive as to produce sickness. Mr. R., however, assures us that this is not the case; that he superintended this, and assisted oftentimes, and that there was not a more strong or offensive odor than is experienced by being near an ordinary manure heap.—The offensive odor, he says, is prevented by the materials used with the water, lime ashes, &c.

Without being sanguine in our expectations that this system of making manure will prove to be of great benefit in the South, we think, nevertheless, that it has sufficient testimony in its favor to render it worthy of investigation on the part of planters. As the *right* for a hundred acres costs but ten dollars, it would be well for a few neighbors in different places to unite in purchasing the said right and thus try the experiment, at a trifling expense to each. And if, after a fair trial, it proves to be what its proprietor claims for it, they can then try it on a larger scale with greater confidence, and if it should prove a humbug, they will have the satisfaction of knowing that they did not pay very dear for their experience.—*Planter.*

Turning Cattle into Fields.—The practice of turning cattle into fields after the crop has been gathered, is considered by many planters as so injurious to the land, that they will not even allow cross-fences, for fear of being tempted to do so. That the tramping of stock on some lands is injurious, there can be no doubt; but we think it is far from being an universal rule. Stiff lands are, of course, rendered more stiff and tenacious by the hoofs of stock, but what is injurious to such lands is often decidedly beneficial to loose, porous soils; and we think this is one of those cases. One of the very best planters we know in the up-country, never permits his stock to run in his fields, and we have no doubt but that his practice is correct, for he plants stiff land; while, on the other hand, we know another who plants light, porous lands in the low-country, who gives his stock the run of his fields, to improve his land by tramping, as well as to improve them. Our object in mentioning these opposite practices, by excellent planters, is to show the importance of studying the character of the soil we cultivate, before adopting what may have proved a most successful practice on the part of others. It is true, with regard to this particular practice, there is another point to be considered, whether the gleaning off of all the vegetable matter from fields, does not exhaust the soil more than is repaid by the feeding of the stock in this way.—We have heard many intelligent planters contend that it does, and it does not become us to say that such is not the case. But we think it would require very few loads of manure to make up all that a hundred head of cattle would glean out of a field, unless the vegetable matter was turned under in a green state, which no planter, with a full cotton crop, can find time to do. And if the stock are penned at night on dry straw and leaves, after running in the fields during the day, the planter will have far more than enough to re-pay what they have taken from his fields, besides what he will gain by the improved condition of his stock.—*Planter.*

THE TOMATO.

We often hear it said, that a relish for this vegetable is an acquired one; scarcely any body at first, liking it, but eventually every one becoming fond of it—if not prepared in every way, at least when prepared in some way or another; or it may hap, raw, without any preparation at all. It has, indeed, within a few years come into very general use, and is considered a particularly healthy article. It delights in rich ground, and is an abundant bearer. No farmer's or cotter's garden should be without it. His family, if like the writer of this, will soon want their tomatoes—once—twice—three times a day—morning, noon and evening! A nice way to keep the plant erect, and the fruit from the ground, is to drive down four stakes, so as to make a square of, say two feet each way, around the plant, and then wrap three or four wisps of straw or matting at suitable distances around the stakes. These will keep the vines from falling, and expose the fruit nicely to the sun for ripening. They will bear till frost.

I have already said I am a great lover of tomatoes; and as this is their season—and as housekeepers, as well as their *lords*, have been invited to throw in their mite to make the Cabinet useful—which, by the way, I take pleasure in looking over—I thought I would cull some receipts from my book. Do with them as you like. Though they may have been published before, they may, perhaps, again be worth their room.

Susanna P.

Newcastle, Del.

Farmers' Cabinet.

Tomatoes instead of Cucumbers.—Treat them much as you would cucumbers. Peal and slice them: season with plenty of salt; pepper and vinegar to your taste.

Tomato Catsup.—To half a peck of pealed tomatoes, put four table-spoonfulls of good salt, four do. black pepper, half do. allspice, three do. mustard, and eight red peppers, all ground fine, and simmered slowly with the tomatoes in sharp vinegar, for three or four hours. Use as much vinegar as to leave half a gallon of liquor when the process is over. Strain through a sieve, bottle and seal from the air. It may be used in a fortnight, but improves by age, and will keep for years.

Stewed Tomatoes.—Peal, slice and stew them slowly. When done, season them, thicken a little, and put in a small lump of butter, and eat them as you would apple sauce. If you have them thus prepared, with good roast beef, properly manufactured—sweet potatoes, and lima beans—and President Tyler should pop in upon you, unexpectedly to dine, you need wish nothing better: you'll find them first rate.

Tomatoes with Beef-steak.—Cut them in two, lay the flesh side upon the gridiron, over pretty hot coals, for a few minutes, turn them, season them well with pepper and salt, and when done, dress them with butter, or eat them with gravy, as suits you best.

Tomato Preserves.—Prepare a syrup by clarifying sugar, melted over a slow fire with a little water, boiling it till no scum appears. Take the tomatoes when quite green, peal them, and put them in cold syrup, with one orange sliced to every two pounds of your fruit: take pound for pound of sugar; simmer them for two or three hours over a slow fire. When a superior article is wished, add fresh lemons sliced, and boil with the tomatoes a few peach leaves, and powdered ginger in bags. Tomatoes, even when ripe, make a fine preserve, treated as above; but unless great care is used in the process, they will fall to pieces.

Tomato Tart.—Roll out your dough very thin, and place it on the plate in which you intend baking your tart, and slice your tomatoes very thin; spread them over the dough also very thinly, take about two table spoonfulls of brown sugar, and one of ground cinnamon bark, spread the two over the tomatoes, bake it well, and you have a delightful tart.

Pickled Tomatoes.—Place your tomatoes in layers, in a pickling jar with garlic or shred onions, mustard seed, horse raddish, red pepper, spices, &c., as wanted, until the jar is filled.—A little salt must also be added, as the layers are put in. When the jar is filled, pour over the tomatoes good cold cider vinegar, till all are covered, then close up tight for use.

Tomato Omelet.—Slice and stew your tomatoes. Beat up half a dozen fresh eggs, the yolk and white separate; when well beaten mix them with the tomato—put them in a pan and fry them, and you will have a fine omelet.

Tomatoes for Winter.—They may be preserved for winter use, by placing them in layers with salt, in jars or tight boxes. When wanted they must be soaked in water, as you soak cucumbers preserved in the same way. Some steam the tomatoes till well cooked, then spread the mass on plates, or other smooth surfaces, and dry them fully, when they can be put in bags and kept in a dry place.

Some are fond of them raw—eating them as we eat an apple.

RYE FOR SOILING.

Crops for soiling during the early spring months, before grass is advanced; in the drought of summer, when it has become parched up; and late again in autumn, after it is injured by frosts, are beginning to be thought of as of more consequence than formerly, and considerable attention is at length directed to their cultivation. For green food in the spring, we know of nothing that comes forward so early as rye, and till it begins to head, there are few grasses more nutritious, especially for milch cows. It is important therefore, that still greater attention should be paid to the cultivation of this grain, for pasture or soiling. From the 1st to 15th of October is the best time to sow rye in the latitude of 40° and farther north, and we trust that every farmer will prepare at least a few acres for the early feeding of his stock. As soon as the mild weather of spring opens, cattle are sure to hanker for green food, and this is the time, if it be withheld from them, that they seem to suffer most for the want of it, and thrive the least. A dry gravelly soil suits it best; but it also flourishes in thin sandy soils, and on stiff clay, when these lands are in good heart. For soiling, an extra quantity of seed should be sown, so as to ensure its coming up thick and covering the ground well. One and a half to two bushels per acre is better than less; and on stiff clay soils, where all the seed is not likely to take, three bushels is still better. But above all, get it in early, so that it may have a good growth before winter approaches; it will then start much quicker in the spring, and make a thicker and more rapid growth.

N. Y. American Agriculturalist.

Do not neglect to save the best and earliest specimens of your crops for next year's seed.

IMPROVEMENT OF CORN, WHEAT, &c.

To the Editor of the American Farmer:

I had the pleasure, a few days ago, of showing you a couple of stalks of corn, *each containing seven perfect ears.* They were taken from a field of twenty five acres, on the farm of Gen. T. M. Forman, of Cecil county, Md. and were a fair sample of the crop. General Forman informed me that he had many years ago adopted the plan of selecting his seed corn, always taking it from the stalks that have the greatest number of perfect ears; and that by continuing this practice he has brought his corn to the high quality represented by the specimens alluded to. This has been uniformly the result with all who have perseveringly practiced it. The first, I believe, to do so, was Mr. Cooper of New Jersey, forty or fifty years since; then the "Maryland twin corn" was produced by some gentlemen on the Eastern Shore: then the Baden corn was announced, and the Mercer corn, also; all were produced in the same way. General Forman intends to measure an acre, which shall be a fair sample of the whole field, and let us know the quantity of shelled corn it shall have produced; this will enable our farmers to compare the product of this corn with that of the common kinds.

A word or two on the utility of attending to such things by our farmers. The wonder is that every body does not do it, and the only reason I can suggest for its not being done, is, that people are not generally aware, that all kinds of plants may be improved by careful attention to *breeding*, just as much as animals are. There are at this day very few farmers so ignorant as not to know that their horses, cattle, sheep and hogs, are wonderfully improved by a judicious selection of breeders. You will scarcely find a farmer now that does not improve his stock by this means. I need not enlarge on this fact. But where are they that improve their corn and wheat, and rye and oats, in the same way?—They are only found here and there, and so seldom, that they are considered prodigies. Every body, almost, when he wants an improved article of this kind, purchases some celebrated kind for trial, which may or may not be what is represented, or may or may not suit his soil or his climate; but never thinks of improving what he has already got. No one ever thinks of crossing the breed of his corn, wheat, rye or oats, and thus improving them; and very few even take the trouble of selecting the best of that which they have for seed. Let me assure our farmers that they can improve their corn and all other crops by *cross breeding*, just as easily as they can their animals. They can change the size and color of the cob; make the corn early or late, yellow or white, soft or flinty; all by *cross breeding*, with no cost and very little trouble.

Generally, all that is done to improve our crops is by manuring the lane and cultivating the growing plants. Now for a moment let us see how it would do in improving animals, merely to feed them well and give them good stabling, paying no attention at all to the selection of breeders. All will admit that stock raised and kept in this way would soon "run out," no matter how good it may have been at the beginning. Well, what is high feeding of stock but analagous to high manuring of land? The one feeds the cattle, the other feeds the crops; neither does any thing more than supply the wants of the individual animal or plant. It does not and cannot change the character or quality of its progeny. When *feeding*, either of plants or animals, does all it can, it does no more than simply keep the individuals as they were, in reference to their natures—it generally produces a good crop, or a fat animal, and that is all.

"But," I anticipate I shall be asked, "*how* are we to improve our corn, wheat, &c. by cross breeding?"

Wheat, rye and oats may all be treated alike—and the process given for one will answer for all. Take several *good kinds* of wheat, bald headed and bearded, blue stem, purple stem, red and white, five or six kinds in all; mix them together thoroughly, and sow the parcel in some good ground at a considerable distance from any other wheat field. At harvest time go into the field and select the best heads, those that are largest, best filled, and that contain the best grains, on the shortest and robust stalks, and keep the seed for another year's sowing. The next year at harvest make the same selection for seed. Continue this selection for two or three years, and then you will find you will have a wonderfully improved variety of wheat. But to keep the quality of this new wheat up to its standard, and even to continue the improvement, you ought always to select a quantity for the succeeding year's sowing in the same way. This is not as troublesome as at first sight it appears to be. A half a bushel or a bushel of seed wheat may easily be selected in this way in a few hours—hours that possibly might not have been devoted to as profitable employment.

The *cross breeding* of corn requires a little more trouble. You have an excellent kind of corn, but it is late in maturing and has rather a large cob. Select some other kind of corn that ripens as early as you desire, and has the right sized cob. Plant your late kind as early in the spring as you can, in every alternate hill, leaving the other hills vacant. At a later period, say 20 to 30 days later, (according to the difference between the two kinds,) plant the vacant hills with the early corn. The place of the experiment should be remote from any other corn field. Cultivate both in the usual way, until you observe the tassels of the early kind beginning to push. Then carefully cut out all the tassels of this early kind—do nothing to the late kind. Watch carefully and cut out all tassels as they appear from this kind. When the corn is ripe, select all the good ears of the early kind for next year's planting. Plant this selected seed in the usual way the second year, and when ripe select the best ears of the earliest ripening. You will find in these ears a variety of grains in shape and color, and of different quality—there will be grains resembling both original parent stocks. Now select the grains that suit you. All the grains will produce a small cob and early corn; but some of the grain on the cobs may be small and inferior like the original parent; therefore on this the third year, select the grains. Generally this third planting will establish the variety; but the better way is to continue to select your seed every year. You may now select seed with a view to increasing the number of ears to the stalk; but take care to avoid selecting small ears simply because there are many on the stalk. If you find a stalk with three full sized ears, it is better to take them than those from a stalk that has four small ones.

By these means corn is susceptible of almost any degree of improvement and change of character; and I am fully satisfied that there is no one branch of agriculture that would so well pay for the small amount of labor and attention required.

SALTING HORSES.—A curious fact is mentioned in Parker's Treaties on Salt. "A person who kept sixteen farming horses, made the following experiment with seven of them which had been accustomed to eat salt with their food. Lumps of rock salt were laid in their mangers, and these lumps, previously weighed, were examined weekly, to ascertain what quantity had been consumed, and it was repeatedly found that whenever these horses were fed on hay and corn, they consumed only about 2¼ or 3 ounces per day; but that when they were fed with new hay, they took six ounces per day." This should convince us of the expediency of permitting our cattle the free use of salt at all times; and it cannot be given in so convenient a form as rock salt, it being much more palatable than the other article in a refined state, and by far cheaper. A good lump should always be kept in a box by the side of the animal, without fear that it will be taken to excess.—*Selected.*

MR. EVERETT'S SPEECH.

Agriculture—its importance—necessity and march of improvement.

Hon. Edward Everett, our Embassador at the British Court, was a guest at the annual dinner of the Royal Agricultural Society, at Derby, July 14th, when upon his health being proposed by the Chairman, Earl Spencer, he responded in the following speech, which embodies truths of which too many professed statesmen are unaware. We bespeak for them a consideration and due application by our own countrymen.

Mr. Everett, upon rising to return thanks, was received with loud and long-continued cheering. He said—My lord and gentlemen, I assure you without affectation, that when I consider the kind manner in which you, my lord, have spoken of me and my country, I am almost overpowered by my feelings, and want words to express them. (Cheers.)

Such a notice, from such a company, of myself and my country, from the intelligent assembly of English noblemen, and gentlemen and yeomen—from you, my lord, who have borne the flag of your country with honor on the sea—(cheers) and who sustain a position of such importance and respectability on shore—sir, I want words to thank you as I ought. You have done me no more than justice, I assure you, in ascribing to me the kindliest feelings towards the land of my fathers. (Cheers.) My lord, I am a great believer in the efficacy of race and blood. I do not think it is confined to the question of Short Horns and Herefords, and South Downs and Leicesters. I believe in the race of men as well as in the inferior animals.(Cheers.) Attached as I am, ardently, passionately, to my own country, desirous to strain every nerve in her service, and, if need be, shed every drop of blood in her defence—(cheers)—I yet rejoice that my ancestors were the countrymen of your ancestors. My lord, the sound of my native language beyond the sea is music in my ears. (Cheers.) I do rejoice that when I speak my own mother tongue I speak in the mother tongue also of a kindred people like that of yourselves—(cheers)—and, my lord, if there is any occasion—if there is any meeting that ought to bring us together as brethren, is it not a meeting of those devoted to the great parent art, the common interest of civilized nations?

Oh, my lord, I believe that if one-thousandth part of the energy, of the skill, of the treasure that have been expended by rival nations in the deadly struggle of what is called "the field," had been employed in a generous emulation to see who would excel the other in the arts of peace, [cheers] I believe my lord, if this had been done, your fathers would have driven us diplomatists out of the field (cheers); at any rate you would leave us very little to do in carrying on angry international discussions. You have been pleased to allude to the important commercial connection between our two countries; it is important, and most earnestly and heartily do I wish it might become more so. (Cheers.) But there is a thought on the subject which has struck me, since I listened to your lordship's instructive speech last evening, illustrating the incalculable importance of agricultural pursuits.

The commerce between our two countries is the largest that is carried on between any two countries on the face of the globe. The annual commerce between Great Brain and the United States is nearly twofold that which you carry on with any other people. The entire annual movement of this commerce both ways—your exports to the United States—your imports from the United States—either of them singly being twice as great as your commerce with any other nation. And yet what think you it amounts to? About as much as the annual crop of oats and beans in Great Britain. [Cheers.] I take the fact from the instructive essay of your worthy colaborateur, Mr. Pusey.

One more fact to show the importance of your agriculture. The whole foreign commerce of Great Britain, in pursuit of which you overshadow the ocean with your fleets, and plant

your colonies in the farthest Islands, is actually less in value than the annual grass crops of these islands. [Cheers.] It does not become me, my lord—I will not say as a stranger—by your kindness you will allow me to throw off that name [cheers]—but as your guest, it does not become me to enter into great details on this occasion; but it struck me in going over your implement yard this morning, that however inactive and neglected you may have been heretofore in the improvement of agriculture, there is nothing to complain of now.

It does seem to me that there is an amount of science, of mechanical skill, of practical sagacity, of capital, and of attention, on the part of the higher orders—of diligence and perseverance on the part of the intermediate and laboring classes, combined, for the promotion of agriculture, that has never been equalled in the history of the world. [Cheers.] And it is a most remarkable fact, if you will allow me to indulge in a general reflection, that till lately all great discoveries and improvements in agriculture seem to have been the product of the very earliest infancy of mankind. Who can tell, my lord, when that instrument that lies at the basis of all civilization, the plough, was invented? Who can tell when man first called in the humble partners of his labor, the horse, the ox, the cow, the swine, the sheep, and took them into profitable alliance with himself?

If you could find out who was the shepherd that first caught the wild dog, and taught him to keep and tend the flock, you ought to rear a monument of brass or marble cenotaph to his memory—a higher monument than was ever raised to hero or monarch. Who knows where the cereal grains or the esculent roots were first cultivated? There is but one of them, as you know, the potato, of which the history is known; all the rest retire back into darkest antiquity. They were cultivated at a time when your ancestors were roaming over the morasses of the now beautiful, free and merry England,[cheers] when our ancestors were roaming painted savages through the land. Ay, when the Romans and Greeks were living on beach nuts and acorns. [Hear, hear.]

It seems in fact, that in reference to the progress of agriculture, mankind has followed that curious law which Mr. Owen alluded to at the council dinner yesterday: the law that governs the ruminating animals in the tropics. He pointed out to us most beautifully that the ruminating animals there have a large fat hump between the shoulders. This is nourished and grows in the first five months of the year when there is plenty of food, and they get along with the hump as well as they can through the seven succeeding months of scarcity. So it seems with mankind with respect to agricultural discoveries. In the very infancy of the race they got this large fat hump between the shoulders, and 3000 years they lived upon little or nothing else. [Cheers and laughter.] The very plow that we read of in Virgil we may now see in the south of Europe.

We see it still in the hands of the peasantry, as we discover it in bas-relief on the sculptured remains of antiquity. It is a most pleasing fact that this revival of the great art of agriculture in these latter days of the world is the work of the Anglo-Saxon race of which you have spoken. It has been left to you, and if you will permit me, to us, living as we do in this ungenial clime, beneath these weeping skies; (the rain was at this moment descending in torrents, and the observation was loudly cheered) it has been left to us to do that which not Italy nor Greece has been able to do, with all their sunny climate.

Yes, and it is the want of those tropical luxuries, those enervating breezes of the south, that has given you, that has given us, that hardihood, that perseverance, that industry, that resolution, that are worth all the spices and all the gold of the tropics. [Cheers.] Yes, it is this that enables you to make that boast in which I hope you will permit me, for my country, to join—

"Man is the noblest growth our soil supplies,
And souls are ripened in our northern skies."

—[cheers.] I beg your pardon for the the length of time I have detained you. I assure you that when these shouts shall be heard across the Atlantic, as they will in 18 or 19 days, they will be echoed from hearts as warm as yours—[cheers.]

NEWBERRY AGRICULTURAL SOCIETY.

The Committee on Wheat submit the following Report:

The land which they regard as being best for the production of that grain, is upland, of a red or mulatto cast. Experience, however, hath shown that it may be successfully grown on any land in this section, not too wet, with the use of plenty of cotton seed as manure. Indeed old land, manured thus, they think preferable, on many accounts, to fresh land unmanured. No land however, which has been cultivated greatly too wet in summer, should be sown to wheat the succeeding fall; as it is next to impossible to make it produce freely, even by manuring, until it has been exposed to the frosts of one or two winters. Other manures, besides cotton seed, may possibly be equal to that, for this grain; but so far as their experience has gone, it is not the case. Stable dung, or any compost of which that forms a considerable part, if applied at the time of sowing, would in their opinion, render the grain much more liable to rust; while they regard cotton seed rather as a preventive against it. On ordinary land, as many cotton seed, in number as there are grains of wheat required, they think would insure a fair crop. Should the land be greatly exhausted however, more might be profitably applied—even to the amount of forty or forty five bushels per acre. Before sowing, the bushes, if there be many, should be cut or grubbed up.

The time of sowing should depend in a great measure, on the kind of wheat to be sown.—The spring wheat will frequently do well, sown as late as the middle of December; whereas all the varieties which ripen late in the season, require to be sown as early as the middle or even the first of October. The condition the land may be in at the time, all other things may be ready for sowing, should always have its influence. The land, they think, cannot readily be too dry, at the time of putting in a wheat crop to permit it to do well; whereas, the chances of a crop would, in their opinion, be materially lessened by plowing in the grain when the land was at all too wet.

The seed, of whatever variety, should be selected from a crop which had matured well, and (at the time of sowing) should be clear of cheet, oats, cockle, &c., as well as all small or defective grains; and to prevent irregularity in ripening, should form itself, but one distinct kind. To prevent a failure from any defect in the seed, they would suggest that a few weeks before sowing, after thoroughly stirring the husk, a small handful be taken therefrom, and after counting and noting the number of grains, it be planted in moist earth, with proper intervals between grains, where poultry or other stock cannot disturb it, and in a week or ten days, the number of stalks which will have come up, when compared with the number of grains planted, will show with tolerable certainty, to what extent the vegetating properties of the bulk can be relied on, and the quantity per acre, in sowing, regulated accordingly. Three pecks (of good Wheat) per acre, on ordinary good land, when sown early, and the grains of ordinary size, they think enough. That which is sown late, having less time to spread, would require as much as one bushel per acre; as well as all very large grained wheat, as it will require more in quantity of the latter, to contain an equal number of grains, with the former.—The quantity per acre of all the varieties, should be greater than suggested, on very rich land.

All seed wheat should be soaked about twelve hours, in a solution of Blue-stone, using at the rate of about one pound to every five bushels of wheat. What is intended for one day's sowing may be thrown in some vessel that will hold water, at night, and the Blue-stone dissolved in a quantity of water sufficient to cover the wheat, and poured over it, stirring it thoroughly at the time, and again before bed time. This, should the weather be unfavorable, would, they think, remain good there for several days. They have never known smut to injure a crop of wheat materially, where the seed had been thus prepared; and feel confident it will operate as a preventive. They farther think it not impossible that the use of the Blue-stone may kill many small and immature grains, which might otherwise come up, and produce chess or cheat. They think cotton seed (when used) should be applied in all instances before the wheat is ploughed in. One of your committee omitted to apply cotton seed to a part of his wheat crop in 1834 or '35, until after the wheat had been ploughed in; and the consequence was, he lost, in his opinion, from three to five bushels per acre. The cotton seed seemed not to have benefitted the crop at all, although applied plentifully.

For ploughing in wheat, especially when cotton seed has been used as manure, they prefer the twister plough, if made so as to turn what land it cuts at each furrow bottom upwards; thus burying the cotton seed and wheat together. They would prefer that the plough should not run more than one and a half, or two inches deep.

The surface of the land should be left as even as possible after the ploughing. For this purpose they recommend the drawing of a large brush, a harrow or roller, over the land, after the ploughing. This will prevent considerable waste in gathering the crop, in addition to the advantage afforded it while growing. Stock of all kinds should now be kept off the land. Even poultry, if permitted to run in considerable numbers, on a wheat field, especially when the crop is young, they think calculated to injure materially the chances of a crop.

One of the causes of failure in a wheat crop, especially early sowing, is believed to be Hessian Fly. Upon that subject, we copy the following from the "Philadelphia Saturday Courier" of May last. We do not undertake to vouch for the correctness of the opinions expressed, but think the article worthy of some consideration.

"As you know this is a wheat growing district, and our farmers may be supposed to know something of whatever concerns the cultivation of that grain. They entertain an opinion with regard to the Hessian Fly and its appearance, which is natural, and which my own observation has convinced me, is in accordance with the truth. It is a big-bellied insect, which makes its appearance in the fall, when the mildness of the winter will admit, especially at that season called *Indian Summer*, and its coming is easily discovered; when it alights upon the ground, it divests itself of its wings, and assumes the appearance of a large black ant, and from its hurried manner, seems to be seeking a place of deposite for its eggs; this it soon finds, either in the crevices of the ground, under a clod, or in the wheat plant; and not always in the latter as is sometimes supposed. After the egg is deposited, the insect seeks shelter for itself in the ground, where it remains during the winter; and either it or its progeny appears again in the spring, to go through the same work of destruction. The opinion is entertained by some, that the egg deposited in the fall, remains to be hatched in the spring,—but not so; nature makes better provision for her creatures, than to cause the egg to be laid in the fall, exposed to the frosts of winter, to be hatched in the spring.—The egg laid in the fall, does its injury to the grain, then or not at all; its effect is then perceptible; and it is the re-appearance of the fly in the spring which repeats the evil. My observation has convinced me that this is the Hessian Fly; and that there is a most infallible remedy for its destruction, as certain as it is sim-

ple—the use of the Roller. A very little care and observation at that season of the year, when the farmer expects its appearance, will discover its presence; and then is the time, whether it be spring or fall, to roll the wheat fields; the weight of the roller not only destroys the insect itself, whose size and shape prevent escape, but destroys also the tender egg, whether deposited in the wheat or elsewhere. I have used the roller for six years, and I have never seen the effect of fly in my wheat, while crops around me have been partially destroyed by it."

A week or two before the wheat begins to head, the bushes and briars being then covered with leaves, and readily seen, should again be cut down. A narrow tool should be used, as it will damage the crop least. All which may get tall enough after that time, to meet the scythe in cutting the grain, will be so tender, as not to be in the way.

The heads should be ripe before the harvest commences. At that period, a careful hand should go through the best spots of wheat, before cradling, and cut off, one at a time, the largest and best heads, gathering in this way when sown, to produce seed for a crop. This, they think, should be sown at the rate of half a bushel per acre, on land well manured with cotton seed. By this means, not only the size of the head, but the size and quality of the grain may, in a few years, in their opinion, be greatly improved, and the wheat clear of mixture. The cutting and binding should be done with a view to saving all, which may very nearly be accomplished, for the foregoing suggestions have been strictly followed. If the wheat is intended for the thrashing machine, and can be thrashed when hauled, the sooner it is hauled the better: by being left out, the straw becomes trash, and (if not hauled in when damped by rain) the head is likely to pull off when entering the machine, and pass through with the grains in it. If the grain is intended to be trod out by horses, the drier it can be got in the better. Wheat should never be hauled in, and packed away with the straw damp, to remain more than a few days, or the weavel will destroy a great deal of it. After the wheat is thrashed, it should have one thorough sunning, if not already very dry, before grinding; if not ground shortly, the sunning should be repeated once or oftener, and put up as warm as the sun will make it. The weavel may thus be prevented from injuring it in the least after thrashing.

If these suggestions are carried out,—keeping in mind all the while the truth contained in the following homely sentences, so applicable to every pursuit connected with Agriculture, viz: "whatever is worth doing, is worth doing well," your Committee believe, that a failure in a wheat crop, with those who sow, would happen but seldom.

PETER HAIR, } *Committee.*
W. HERBERT, }
S. C. Temperance Advocate.

CORN STALK SYRUP.—Mr. H. J. Chalmers, of Monroe county, has politely left at our office, a bottle of SYRUP, made from the common Corn Stalk. We have *tested* its quality, and can pronounce its saccharine flavor to be milder and richer than any of the Louisiana Syrup we ever tasted—it has nothing of the acidity often detected in other Syrups, and particularly in molasses; but leaves upon the palate a pleasant and agreeable sensation, that irresistibly makes you smack your lips.

Mr. Chalmers refers us to a communication he sent the Messenger, shewing his experimental operations in making the Syrup, but as it has not yet appeared in that paper, we are deprived for the present, the gratification of presenting it to our readers.

Mr. C. informs us, that he is perfectly satisfied he could have made Sugar; but he had no shallow kettles for the purpose, nor could he procure any. He is so well pleased with the little experiment he has made, that he intends going more extensively into the business next year, and patriotically exclaims, "I trust the day is not far distant when the Planters of Georgia will become independent of the West Indies and Louisiana, for their Sugar and Syrup." Let our Planters but enter upon the business with the same spirit and zeal that actuates Mr. Chalmers, and the day will not be far distant when his hopes will be realized—may he live to see it.

Macon Telegraph.

CORN STALK MOLASSES.—Mr. H. J. Thompson, a thorough going, enterprising planter of this county, called at our office a few days since to exhibit to us a specimen of molasses, made by himself from the common corn stalk. We have given the article a fair test and do not hesitate to pronounce it equal, if not superior to the best "sugar house molasses." It is equally as transparent, and in flavor resembles very much the "Florida Syrup," an article which is manufactured from the juice of the cane, and which, where it is known, is esteemed superior to any other for table use. Mr. Thompson informs us that he was induced to make the experiment from reading an article in our paper last spring. It was then too late to plant for the purpose, and he resolved to set aside a small patch which had been planted in the ordinary way, for the purpose. From this he removed the ears as they put forth, and allowed it to stand until the fodder was ripe. Having constructed a mill for the purpose, he expressed the juice from the stalks and boiled it in a common kettle, reducing about seven gallons to two, which produced the fine specimen of molasses which he has exhibited to us. Not having planted his corn for the purpose, Mr. T. is unable to come at any thing like a very nice estimate of the amount which any given quantity of land would yield—but he assures us that the test which he has given the matter, in the manufacture of the twenty-five or thirty gallons which he has made this year, has not only satisfied him that the best of molasses can be made from corn stalks, but that he can obtain a better return for his labor from its cultivation than from any other crop. A specimen of the molasses made by Mr. Thompson may be seen at this office.

We have been informed by Col. Jno. B. Walker that he is now making some experiments in the Corn Sugar and Molasses. The Colonel is desirous of ascertaining the yield, and with this view has scarcely measured the ground planted for this purpose. We hope to be able to give our planters the result of Col. Walker's experiments in a few days.

Madison Miscellany.

CORNSTALK MOLASSES.—We acknowledge the receipt of a bottle of what we should have pronounced, had we not been informed to the contrary, first quality *Sugar House Molasses*, it having the appearance of that article. It was manufactured from corn stalks, by James S. Pope, Esq., an enterprising planter and farmer of this district, who has spared neither pains nor expense in bringing to perfection an experiment, which has so often been tried, but we have never heard of its having been brought to so successful an issue in this district. We wish him success in his future experiments. The following explanatory note accompanied the bottle of molasses.—*Edgefield Advertiser.*

Mr. W. F. DURISOE—Dear Sir—I take the liberty of requesting you to publish for the information of the public, an experiment which I have lately made in extracting syrup from the corn stalk. I allotted about seventy hills square for my experiment, from which I made about twenty-five gallons of syrup. I present you with a specimen, which will enable you to judge of its quality. I deferred too long in stripping the shoot from the stalk. I think if the shoot had been stripped in time, the yield would have been increased. I am inclined to think that an acre, if in a high state of improvement, and well cultivated, can be made to yield *at least* seventy five gallons. The corn should be drilled, and the drills about three feet apart.—Planting in this manner, will prevent the corn from shooting (so it is said,) and will enable the stalk to retain the juice. It is evident that the shoot should not be permitted to remain on the stalk until the grain begins to form.

Yours, respectfully,
JAMES S. POPE.

IMPORTANCE OF AGRICULTURAL ASSOCIATIONS.

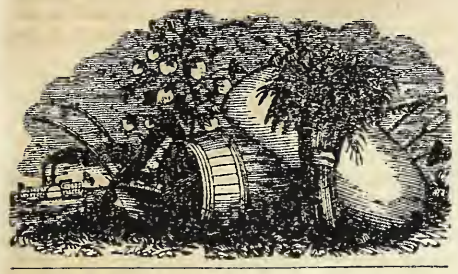
Again, as agriculturists, we have been remiss in associated efforts for the advancement of our calling. When acting as politicians, we are sufficiently awake to the importance of concentrated efforts. On moral and religious topics, none of us forget "in union there is strength."

The benefits arising from agricultural associations, experience has demonstrated to be—the more general attention to the subject of agriculture, which they are the means of exciting through the entire mass of the farming community where they are situated; the emulation which they excite among members to excel; the means which they are of introducing improved varieties of animals and products, and improved processes of breeding and cultivation; and, finally, in the information which they diffuse by actual inspection and comparison of animals and products, which their fairs call together.—We have only to refer to sections of country where properly constituted societies have been in efficient operation, to witness the existence of these effects. The Highland Society of Scotland has been founded a little over half a century—59 years, if we mistake not—and it is not too much to say, that it has revolutionized the agriculture of that whole country. An inhabitant of the more fertile sections of New York, where nature repays the least and the most indifferently directed efforts so bounteously, can scarcely conceive the disadvantages under which the agriculturists of the Scotch Highlands (if the recently disarmed retainers of the Highland chiefs, whose hands were far more familiar with broadsword and firelock than with the reaping hook or plough handle, could be termed agriculturists) labored fifty years since. Sterile mountain and unprocubtive moor, extensive marshes and wet cold clays, occupied a greater portion of the country; but now Judge Buel states, on the authority of Sir John Sinclair and Professor Lowe, that the acreable products of Scotland double those of our Atlantic States, and he assigns the principal part of this change to the agency of the Highland Agricultural society. England, too, has derived immense benefit from similar associations, whose history and progress would be highly interesting and instructive, did time admit of the examination. The Berkshire, Worcester, and Essex Societies, in Massachusetts, have met with the most decided success, and annually increase in numbers and in spirit. Each pay out annually, in premiums, upwards of a thousand dollars, half of which is drawn from the State Treasury; and we have the best authority for stating, that these sums would not pay 3 per ct. on the increase of agricultural products which they have been the means of occasioning.

The increased interest to the subject of agriculture, and the spirit of emulation excited by these associations, never fails to exhibit itself in the most marked manner. There are few neighborhoods where there are not one or two individuals who will attempt to keep pace with the advancing march of their profession. Others are gradually incited by their example, or the fear of being surpassed by them, to similar efforts. Improved breeds of cattle, sheep, swine, horses, &c., as well as improved processes of cultivation, gradually extend.

New Genessee Farmer.

LADIES, VEIL NOT YOUR FACES.—A celebrated writer on sight, says that the wearing of veils permanently weakens many naturally good eyes, on account of the endeavors of the eye to adjust itself to the ceaseless vibration of that too common article of dress.



WEDNESDAY, SEPTEMBER 27, 1843.

BACK NUMBERS.—All new subscribers to the 'Southern Cultivator" can be supplied with the back numbers.

IMPROVEMENT OF CORN, &c.

As the season for harvesting this valuable crop is now near at hand, we commend to the reader's attention the article under this head, in this number, which we copy from the "American Farmer." The labor of selecting seed corn in the manner suggested, is indeed small when compared to the immense value of the seed over that ordinarily obtained from the crib at planting time, and we look forward to the day, as not far distant, when this mode of selecting seed will be very generally adopted by our planters.

CULTURE OF CORN.

We have to thank our friend Rutherford for the subjoined letter, giving his experiments in the culture of corn on a new system. We are the more obliged to him, who we know to be a young farmer, because of the excellence of his example to the old men, in giving us the results of his experiments—an example which we trust will not be lost on our planters generally. The experiment speaks for itself, and we commend the letter to the careful consideration of our readers—let them reflect upon its truths and improve upon its suggestions.

CRAWFORD CO., Sept. 15, 1843.

MESSRS. EDITORS—The communication which I am about to make, I designed making to the Albany Cultivator last year, and would have done so had it not been for my aversion to appearing in the public prints. I at several times thought of making the communication over a fictitious name, but reflected that facts are not so apt to be received *as such*, unless a man vouches for their truth in his own proper name.

It may be proper to say, in the outset, that I am cultivating land on Flint river, which I settled some four years since for my father, and which, in the common language here, is "as rich as land ever gets to be."

Last year I planted for experiment one acre of corn in the following manner:—The ground was first broken very deep and then laid off *two feet* each way—the corn planted in the checks and covered with the foot. When it was up about half leg high, I had it flat weeded and thinned to one stalk. When silking I had it flat weeded again, and this finished the cultivation—it never having been plowed at all. About the time the corn was grown, a severe wind prostrated it in several places, so that I feared my experiment would fail at last. In addition to this disaster, it being in an exposed situation, the squirrels destroyed a good deal—the outside row was, I think, entirely consumed. At a proper time I had what was left gathered, shucked out, and measured the ears in a barrel in the same manuer as we purchase and sell corn. I had one barrel shelled, and as I had no measure upon which to depend, I weighed the corn thus shelled. According to the weight of this barrel, the produce of the acre, as gathered, was five thousand one hundred and four pounds.

Now farmers differ as to the weight of a bushel of corn. In the Southern States it varies from 50 to 56 pounds; the latter being the maximum weight. This I allowed, and you will perceive, upon calculation, that this will make it 91 bushels and nearly half a peck.

I have given you the result of an experiment tried under many disadvantages. I will now give you the reasons which induced me to plant as I did. It is a fact well known, that corn matures better in a colder climate than ours, and from this I inferred that it suffered too much from the intense and *collected* heat of the sun in our climate. This is one reason why I planted so close, for when grown in midsummer, the ground, and therefore the roots, would be protected from the sun by the shade of the corn itself. Another reason was, that in appropriating a given number of stalks to the acre, they had better be planted at equal distances from each other in every direction, so that the roots of one stalk will not interfere with those of another. By this system you make it more profitable, as every particle of earth will be reached by the roots, and no portion of soil be free from effort while other portions are overtasked.

Another reason was, that when planted so as to shade the ground, (strange as it may appear,) it would better stand a drought, by preventing the largest portion of a shower from evaporating, as is the case where the sun has free access to the ground. That this idea may not appear so novel, I ask you to reflect that the spots which remain moist for the longest time in the woods are those which are covered with the densest growth.

Another was, that it would save labor in the cultivation; for when the corn is high enough to shade the ground, weeds and grass cease to flourish. And still another reason was, that it saved the necessity of cutting the roots with the plow. I know this is a controverted point among practical farmers; but I would just as soon expect that an animal would be more thrifty by having his limbs broken or his mouth lacerated, as to suppose that a plant would be more vigorous in consequence of having its leaves or roots injured. The latter, vegetable phisiology teaches us, serve as the mouth, and the former as the lungs, of plants. It has again been objected, that such close planting prevented the corn from getting *air*, which was necessary for its health. It has seemed strange that this objection should have been urged, for if a philosopher were experimenting in pneumatics, he would hardly say his receiver was "*air-tight*" if it had a crack of *two feet* in it. Finally, Messrs. Editors, we may theorize on the subject as much as we please, and there may be as many objections urged as it is possible to produce, yet unprecedented success and a full "crib" will answer them all—at least to my satisfaction.

There were two other acres connected with the one upon which the experiment was tried, part on one side and part on the other, planted and cultivated in the usual way. The product of both together scarcely equalled the one I report, though the corn had been worked oftener. This year I have planted some 8 or 10 acres after pretty much the same plan, and it is decidedly the best corn I have; the freest from weeds and grass, and will doubtless produce double of any other corn on the plantation, though the land is equally good elsewhere.

I am your friend, truly,

WILLIAMS RUTHERFORD, Jr.

NEWNAN, September 16, 1843.

Messrs. EDITORS—I see in the Cultivator, No. 15, page 114, a communication from Mr. John Farrar, of Putnam county, describing his mode of making corn. He states that his land is broken and stony, and to prevent them from washing, he ditches his hill sides. Would Mr. Farrar be so good as to inform us, through the Cultivator, his manner and mode of ditching; how wide, deep, and what distance apart they should be, and all the practical information he possesses on the subject? As the lands in our county are broken, and of a coarse sandy loam, and washes rapidly, if it could be prevented by ditching, the value of it would be considerably enhanced.

Would you give us in the Cultivator the price of plows, corn-shellers, straw-cutters, &c. in the Augusta market, and oblige yours, &c.

A. B. L.

NOTE BY THE EDITOR.—In answer to the enquiry of our correspondent, A. B. L., we will reply as distinctly as possible. A good article of Straw Cutters can be had at from $20 to $50; Corn Shellers, from $10 to $20, and Plows from $3 50 to $15, at the Agricultural Repository of Alexander Philip of this city.

THE FARMER'S PROFESSION.

The following is an extract from an address delivered before the Oneida County [N. Y.] Agricultural Society, by Anson S. Miller, Esq.

Princely patriarchs, prophets, kings, philosophers, the great of all ages, have honored agriculture with their particular regard. The pursuit is indeed laborious; but labor is no longer an evil, except in its excess. The cheerful performance of labor by man, has freed it from its original curse. It is now a boon of heaven—the condition of unnumbered blessings. The farmer's calling is full of moral grandeur. He supports the world—is the partner of nature, and peculiarly 'a co-worker with God.' The sun, the atmosphere, the dews, the rains, day and night, the seasons—all the natural agents—are his ministers in the spacious temple of the firmament. Health is the attendant of his labors. The philosophy of nature exercises and exalts the intellect of the intelligent farmer.—His moral powers are ennobled by the manifestations of supreme love and wisdom in every thing around him—in the genial air, the opening bud, the delicate flower, the growing and the ripening fruit, the stately tree—in vegetable life and beauty springing out of death and decay—

and in the wonderful succession and harmony of the seasons:

"These as they change, Almighty Father! these
Are but the varied God. The rolling year
Is full of Thee."

We are now beholding a mighty moral revolution. Hitherto, glory has been found in the *destruction* rather than the *preservation* of man. The history of our race is a history of wars.—An age of peace and philanthropy is arising upon us, in which renown will be sought in usefulness. Justice will yet be fully done to the benefactors of mankind. Young, and Watson, and Clinton, and Buel, and others, both of the dead and the living, who have laid society under enduring obligations, will receive their share of the public gratitude. How dim, how fleeting is the fame of the mere warrior, when contrasted with that of the philanthropist.—What wasting battles, what fields enriched with carnage, what spoils of victory, or what splendid triumphs, could confer the lasting glory of De Witt Clinton!

REMEDY FOR SMUT IN WHEAT.

Mr. Editor:—Your journal circulating extensively through the wheat growing portion of our own State, you will permit me to enjoin upon the wheat producers the necessity of brining and rolling in lime the seed bofore sowing, with a view to eradicate smut. This remedy for a serious evil, magnified the current season to an alarming extent by neglecting to practice it, is not new to the intelligent book-farming husbandman; and my only object now in addressing you, is to confirm the testimony of others.

I will briefly state, for the benefit of all concerned, the proof as practised last year by myself. I used two ordinary sized wash-tubs, one of which contained some four or five pails of strong brine, and upon the top of the other tub (resting upon two slats) was placed a bushel and a half basket of wheat. The brine was then poured upon the wheat, and was quickly deposited, by leakage through the basket into the tub below it. On emptying the basket, the same brine was used to saturate a similar quantity, and so on to the amount of ten or twelve bushels. If my memory serves me right, I used about a bushel of fresh slacked lime to that quantity of secd. After thus preparing it was carted to the field in barrels. The seed was sown upon the field which you saw, Mr. Editor, in July, when I had the pleasure of meeting you here, and I am certain of the fact, that not a head of smut was detected when harvesting it.

In regard to another field of some twenty acres, not having any more lime on hand when it was sown, I neglected to prepare the seed as above, and the consequence was, there was some smut, but not to that extent of some of my neighbors' fields. I shall take special care this season, to brine and roll in lime all my seed, and if my brother wheat growers desire to sell the "clean thing," and what is of greater consequence, make, if possible, their wives and daughters more amiable by having *white bread* —they will do likewise.

A word more. Your estimate sir, that the field which you saw would go 25 bushels to the acre, will be verified beyond a doubt. In many heads I counted from 80 to 100 kernels, and a few that I selected measured six inches in length. The variety is the red chaff bald.

L. A. Morrell.

Lake Ridge, Tompkins Co., N. Y.

New Genessee Farmer.

New Dish.—The Mississippi Valley Farmer says—By paring, quartering and boiling cucumbers, a dish may be obtained in every respect similar to asparagus.

Useful Hints.—Never enter a sick room in a state of perspiration, as the moment you become cool your pores absorb. Do not approach contagious diseases with an empty stomach; nor sit between the sick and the fire, because the heat attracts the thin vapor.

AUGUSTA MARKET.

Cotton.—In resuming, to-day, our brief notice of our market, which will be continued during the business season, we are gratified to be able to announce to our friends a decided improvement in the value of our great staple.—For some time the northern markets have been very much excited, because of the increased demand among the American manufacturers for goods, and the consequent short supply of the old crop in this country, which circumstance, of course, advanced the prices in all the American markets, to a rate quite as high as the English. Upon this excited state of our markets, came the late news, per Caledonia, advising of an advance in Liverpool of ⅛ to ¼d upon all descriptions—produced principally by the unfavorable accounts, from this side, of the growing crop; although it must be admitted that the general improvement in business, and the increased demand for cotton yarns and goods, has likewise had its influence; and, as a consequence of this news from abroad, our own market has advanced ¼ @ ½ cent ℔ lb. within the last few days. We now quote 6 @ 8¼ cents for old, and 8 @ 8½ cents for the new crop, with an active demand. Whether these prices will be sustained, will, in a great degree, depend upon the extent of the growing crop, and the continued demand for goods and yarns, both in England and this country, of which our readers can judge as well as ourselves. We are, however, of the opinion, that the interests of the planter are *generally* better protected when he gets his crop to market early and sells—*particularly* if he meet an active demand.

Dry Goods, Groceries, &c.—The indications of a return of more prosperous times is, perhaps, not more perceptible in any department of business than the mercantile; and we are gratified to announce to our country friends, that our merchants are fortifying themselves in every department with abundant supplies to meet the demand of their country friends. The stock will be ample, and the prices are generally ranging low.

Bagging and Bale Rope.—The supply of both these articles is heavy, and sales to a heavy extent are daily made. Gunny Bagging, which is most enquired for, sells from 19 @ 20 cents; Dundee at from 16 @ 20; Kentucky 17 @ 18 cents; and other descriptions at proportionate rates. Manilla Rope 9 @ 10; Kentucky Hemp 8 @ 9 cents.

Money—Central Bank notes sell from 9 @ 12 ℔ cent dis. State 6 ℔ cent Bonds at 72 @ 74 cents.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, Jr.,
No. 232 Broad street, Augusta, Ga.
August 30. 18-tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, Jr.

BOMMER'S PATENT MANURE.

THE undersigned is the Agent of Messrs. Abbett & Co., for vending rights to individuals for making and using the above named Manure. By reference to the following advertisement of Messrs. Abbett & Co., the prices may be ascertained. All orders addressed to me, *post paid*, at Sparta, Ga., will receive prompt attention.
Aug. 30. 18-tf R. S. HARDWICK.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days*. And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent $6
Farms up to 100 acres 10
" from 100 to 200 acres 15
" " 200 to 300 " 18
" " 300 to 400 " 20
" over 400 acres in any one farm 25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., OCTOBER 11, 1843. No. 21.

From the Transactions of th N. Y. State Agr. Society.

SUBSOILING—SUBSOIL PLOWS.

By C. N. BEMENT, Albany.

Heretofore the farmers of this country have cultivated a soil enriched for ages by the yearly addition of a fresh stratum of mould. From the first existence of vegetation upon the dry land, decayed plants, leaves, &c., have continually furnished a supply of manure, which the winds and rains have liberally spread abroad. As the supply was annually greater than the consumption, the earth, unexhausted by its productions, increased in fertility. The thick layers of vegetable mould which covered the face of the earth, was a storehouse of food for plants, and this quality increased by the conversion of wood into ashes by clearing. It is not wonderful, then, that for some years newly cleared settlements should abound in produce and require little more labor than that of plowing and reaping; for during this period the provision is wasting which for centuries had been accumulating. But the time will come, and indeed has already come in many sections, where the soil has been exhausted, and is took weak of itself to make plants grow with their former luxuriance. The grand question now presents itself, "how shall this soil be renovated and brought back to its former richness and fertility?" My answer would be, by breaking the under crust, opening and stirring the subsoil, by which means it so alters and disposes the earth in which plants are rooted, that the radigals shoot more easily and more extensively through it, or in other words, it becomes a better filterer for straining and applying nourishment to their inhaling or absorbing vessels.

It is a well established fact or axiom in agriculture, that the deeper the soil is, the more favorable will it be for the purposes of cultivation. To produce this desideratum, several plans have been adopted, either by thoroughly trenching with the spade, or by the use of the subsoil plow. Air and water are chief instruments which nature makes use of to enrich the earth.

It is by close attention to passing events that any desired object can ever be obtained. As far as experiments have been made, we find the earth liberally affording its produce in tenfold quantity, and the land that now supports an hundred inhabitants, may give equal enjoyment to a thousand. But in this stage a well managed farm must be carried on with more labor, more expense, and more exact skill. The most profitable system of culture is that which pays the greatest per cent on the money laid out in cultivation, while the land is yearly increasing in its productive powers, is a truth which no one will attempt to deny.

I have, for the last four or five years, had my attention directed, by reading in the agricultural journals, to the great benefits derived from subsoil plowing in England and Scotland, and have felt very anxious to obtain an implement for the purpose. For the last three or four years I have been making some experiments with merely an apology for a subsoil plow, as it only penetrated about five inches below the bottom of the furrow of the common plow, and the share was thin, flat, and only three inches wide at the broadest part; still, with this simple, and I might almost say, inefficient machine, I could see a very perceptible difference in the appearance of the crop, especially in a drouth. In 1841, I made an experiment in a field of corn, a part of which I subsoiled with my skeleton or apology for a subsoil plow, stirring the under soil only to the depth of five inches; in that part of the field where the under crust had been broken, the corn maintained a healthful, dark color, while that adjoining, which had not been stirred with the skeleton plow, turned yellow, leaves curled and looked sickly. In fact, the difference was so great that it was noticed by those passing, although some distance from the road. I also tried it for my carrots and beets, with the same decided effect. I have tried it on a stiff loam, and on soil inclining to sand, with equal success. This I was not prepared for, as I supposed such soils would not be benefited by the operation; but on examination, I found the subsoil, which had not been reached by the common plow, very compact, and nearly as hard as a beaten track on the surface.

As for myself, and from my own experience, I entertain not a doubt of the utility of deep plowing; not, however, by turning up the under soil, but by following in the furrow made by the first plow, with a real subsoil plow, which, if properly constructed, pulverises and stirs the earth from twelve to fourteen inches. Indian corn, and all tap-rooted plants, in such a mass of loosened earth, would not, I am confident, suffer much by an ordinary drouth. Like a sponge, it would absorb a vast quantity of rain water, and become a reservoir to supply the wants of the plants. Nothing is more common in a dry summer, than the rolling of the leaves of corn; and the circumstance is often mentioned as an evidence of the severity of the drouth.

There is another advantage in subsoiling. If the season is wet, it has the effect of partially draining the land, and causes the water to settle and carry with it any vitriolic or other noxious matters.

I am not aware that subsoil plowing has as yet, in this country, received much attention; but from my own experience, and several experiments made by different persons in different sections, and with very indifferent implements, the results have been such that I am led to believe that it will prove of very great advantage on old soils that have been long under cultivation.

E. Phinney, Esq., a very spirited and successful farmer in Lexington, Mass., in a letter published in the New England Farmer, in speaking of an experiment made with a substitute for a subsoil plow, in a field of carrots, says, "A part of my crop of carrots was sown upon the same land appropriated to that crop last year; no more manure was applied than in the previous year, and notwithstanding the very severe drouth which greatly injured most of our root crops, my crop on this piece of land was nearly double that of last year. There is no known cause to which I can attribute this great increase of the produce, but the use of my new constructed substitute for a subsoil plow. The soil was stirred to the depth of fourteen inches; by this means the roots of the carrots were enabled to strike deep, and thereby not only to find more nourishment, but to overcome, in a great measure, the effects of a very pinching drouth."

It is stated in the New England Farmer, "that B. V. French, Esq., of Braintree, Mass, raised the past season, over 22 tons per acre of white carrots, on ground not particularly well prepared for roots. He attributes this great crop principally to the use of the subsoil plow on the land the previous season."

The subsoil plow has been tried in Pennsylvania and Delaware, but I have not as yet seen any account of its effect on the crops. For deep rooted plants, no one, I think, will pretend to gainsay. Why do our gardens produce so much more to the acre than our fields? Is it not, in a great measure, owing to deep tillage and mixing the under with the upper soil?

Mr. Smith, of Deanston, to whom is awarded the credit of first successfully introducing the subsoil plow, in a lecture delivered before the Royal Agricultural Society of England, in July last, says, "When I first began to cultivate my own farm, although I had put in the drains, I found they were not so efficacious as I at first expected; and I then began to think of stirring up the subsoil, which gave rise to the idea of a subsoil plow. I thought I must construct an instrument which would execute the work with the least possible power. I made my plough very strong, and of that form to which the least resistance would be opposed, at the same time taking care to have sufficient power fairly to stir up the soil.

"I will here explain the principle of the subsoil plow, because I have found that many persons, although seemingly acquainted with it, have not a proper notion of the principle on which it is based. The great principle is, that there are many subsoils, which, though capable of being converted into a good soil, yet it brought up and mixed with the active soil, will so far deteriorate it as to make it for some time sterile. It therefore occurred to me, that the great point would be to stir up the subsoil, still retaining the good soil on the surface. Stirring up the subsoil would, in the first place, very much facilitate the escape of the water into the drains; and secondly, in consequence of the passage of the water through the stirred up subsoil, and the attendant admission of air, it would be so acted upon as to be converted into good soil, while, at the same time, I was having all the advantages of working the active soil as before."

Having treated of the process, and noticed some of the advantages derived from subsoil plowing, I will now endeavor to give a description of some of the implements made use of for that purpose, three of which are of European, and one of American manufacture. In proof of the estimation in which subsoiling is held in England, I would state that no less than eight subsoil plows were entered for competition and exhibition at the Fair of the Royal Agricultural Society, held in Bristol in July last.

The subsoil plow is not a new invention, but was in use in England more than fifty years ago, and recently brought into prominent notice by Mr. Smith, of Deanston, Scotland. In Dickson's Report of Lancashire, is the following notice of the "Miner or deep-stirring plow:"

"There is another tool of the plow kind, somewhat similar in construction, which was introduced into the country about the same period as the 'Trench plow.' It simply consists of a plowshare firmly fixed to a strong beam by means of a strong sheath and handle, without any mold board. It is usually drawn by four or more horses, being made to follow in the furrow of the common plow, so as to penetrate into,

loosen and stir up the under soil, without turning it up, to the depth of from eight to fourteen inches below the track in which that plough had gone."

The following description of it is taken from Mr. Morton's prize essay, published in the "Farmer's Magazine," (London,) of July last. Mr. Morton says, "Smith's subsoil plow consists of the ordinary frame-work of a plow, without the mold board, made strong enough to stand the shock and the strain to which an implement requiring the force of four or six horses to work it, must be subjected. The frame-work is of iron, and about 15 feet long. A sole-plate, on which a feather-shaped or pointed sock slips, is attached to it by means of two uprights or curved coulter. The height of the plow, when held in a working position, from the sole-plate to the beam, is about 22 inches. From the furrow side of the sock, a spur projects, over which the mass of subsoil cut by the coulter and share is raised and broken, and falls down again."

Now the American subsoil plow, made at Worcester, Mass., by Messrs. Ruggles, Nourse & Mason, differs from Smith's in several particulars. The handles and beam are made of wood, reduced in length, and in fact the whole implement is reduced in size, which makes it much lighter, and can be turned in the same space as the plow which precedes it. In place of the spur, as in Smith's, this has an inclined plane, which rises from the feather of the share, and extends back to the heal of the plow. It is about three inches wide, lies against the upright, and rises to the height of six inches behind. By means of a slat in the point of attachment, it can be raised or lowered at pleasure. With this inclined plane the soil is raised, pulverized, and partially mixed, leaving it in a loose, friable state, without bringing it to the surface. By this simple contrivance the draft has been so much reduced that two common sized horses are amply sufficient to work it in a stiff, loamy soil, from eight to ten inches below the bottom of the furrow of the plow that precedes it, but it must be free from roots and large stones. The greatest improvement however, and especially at the present time, is the price at which they are offered, being less than one-fifth of the price of the imported article. One of Smith's was imported in 1840, by Messrs. Ellis & Boston, of Boston, at an expense of $80. D. D. Campbell, Esq., of Schenectady, imported another about the same period, or soon after.

I have tried the Worcester subsoil plows, and can say I was much pleased with its performance, and more particularly with the ease in which the horses performed their work. Now, if the plow turns up a furrow six inches deep, and the subsoil plow penetrates and loosens the subsoil ten inches below the first plow, we have at least sixteen inches loosened soil, which in the common method of plowing, and allowing that the plough lays the furrow two inches higher than the depth of the cut, we have then but eight inches of loose soil for the bed of the plant.

The expense of cultivating by subsoil plowing, must be necessarily much increased by the present mode, as it requires an extra hand and team to go over the same ground, and at the same time of the first plow; and to diminish the expense of the operation of subsoil plowing, and to adopt them to the wants of the small farmers, several attempts have been made, in England, to combine the two implements in one. The first of these, by Mr. Pusey, called the Charlbury Subsoil Plow, "combines in one implement," says Mr. Morton, "both the plows used in the operation of subsoiling. It not only stirs the subsoil, but opens the furrow in which the subsoil plow works. It consists in the attachment of a strong tine, similar to those used in Biddle's Scarrifier, to the common plow, in a position in which it acts after the furrow slice has been turned."

"This implement," continues Mr. Morton, "doing all the work, requires, according to an experiment recorded there, less force to work it than the subsoil plow, doing only one portion of the operation. It cannot, however, be so efficient in thoroughly stirring the subsoil as the original plow." The other attempt at diminishing expense of subsoil plowing, is by Mr Armstong, of Stirlingshire, for which he received premiums from the Stirlingshire Agricultural Society, and from the Highland Society.

The following is a description of it, as given by Mr. Smith, at an agricultural meeting. It appears that the inventor has adapted the principle of Wilkie's turn-west plow to Smith's subsoil plow; and if I understand the principle of it, it is just what the American farmer is in need of, as one hand with one team can perform both operations.

The general frame work is that of a subsoil plow, rather under the medium size, and to it is attached a hinged mould-board, similar to the mould-board of Smith's hill-side or turn-west plow. By means of this arrangement, the plow can be used for removing the furrow preceding the operation of the subsoil plow, and when the furrow has been removed, the mould-board being moved upon its hinges, from its working position, rests over the beam of the plow, whilst the instrument is used for subsoiling in the bottom of the furrow just removed. Thus the operation of removing the furrow and subsoiling, can be alternately performed with the same implement, with the same plowman, and the same team of horses, by a single movement of the mould-board, which is done in an instant by the hand of the plowman, at each turning. The additional weight of the mould-board serves to keep down the plow whilst subsoiling in different grounds. The judges consider this implement well contrived, and as being an important boon to the small farmers, and as certain to give great facility to the extension amongst them of the admirable system of subsoil plowing.

From the Columbia (S. C.) Planter.

FAIRFIELD, August 30, 1843.

DEAR SIR—I feel ashamed of not having yet complied with your request, that I should send you a treaties on the manufacture, application and effect of manure. I will, however, compromise with my conscience, by promising to do so in a week or two. The fact is, I am so conscious of devoting less attention and labor to that department of plantation economy, than its importance demands, that I feel a repugnance to seeing my deficiency formally and mathematically computed. My present impulse is to discourse on the inexplicable subject of rust in cotton, and I will not thwart it.

In this section of country, we have two species of rust—the red or common rust, and the brown or French. I cannot give you the derivation of the latter term, but it is of general prevalence in this neighborhood. The red rust is that to which all varieties of land in this district are more or less liable; and the brown rust, or French, that which is only found on black-jack soils, and on the flat lands of the description of those on Dutchman's and Wateree creeks.

As Humbug jr. affirms, many theories have been adduced to account for the origin of the red rust, the partizans of each believing firmly in his own favorite, and denouncing those of others; and he accordingly treats as an absurdity, a creed of mine, which I consider I have incontestibly proven by an experience of nine years.

I commenced to till my present lands, and at the same time to cultivate the short staple cotton, nine years ago, under the tutorage of an observant, experienced and skilful overseer. In the early part of the summer, he remarked to me, that we should have to keep our cotton fields free of poke weeds and briars, if we meant to escape rust. This being a new idea to me, I of course ridiculed it, and so unmercifully too, that, as he afterwards told me, he forthwith determined that I should purchase belief by expensive experience. Accordingly, towards fall, he carried me to three several spots of rust in as many different fields, which he had contrived to produce by leaving poke-stalks in or around stumps, which happened to be there located.—They were the only spots of rust I had in my crop, and from every other portion of it had the poke been carefully eradicated. This coincidence staggered me, and its repetition for nine consecutive years, has confirmed my faith.

In riding by the fields of my neighbors, I have seen poke-stocks suffered to grow among the cotton, and have predicted to a companion (correctly, as it was proven,) that rust would be the consequence. On the other hand, I have first seen rust, and on searching for it, have found poke.

I do not say that rust may not originate without the presence of poke; nor do I believe that, like the celebrated upas tree, it exudes poison, deleterious to surrounding vegetation; but simply that poke, briars, strawberries, and perhaps other plants, are more liable to the disease than cotton; and having first become affected, communicate the disorder to their more healthy neighbor. Where poke has been repeatedly cut down in the early part of the season, and is suffered to grow at a late date, I believe it is harmless; for it does not appear to be liable to the disease till it has reached maturity, and commenced to decline.

A friend of mine spent a part of the last summer in this vicinity, and occasionally delighted me with a visit. At our first interview, he began, in unmeasured terms, to denounce the folly and superstition of "some ignorant citizens of the district," in believing that poke could produce rust. Like St. Peter, I was at first ashamed to confess my faith in so despised a doctrine, and, if I did not deny, certainly did not avow that I was a disciple. At each subsequent interview, I was gratified to observe that the opposition of my friend was melting away under the influence of accumulating proof, till at length, when I rallied and came to the rescue, his offensive warfare degenerated into mere defence of his doubts, and he finally determined to risk his remaining strength upon the issue of a single experiment, an opportunity for which then presented itself. In the midst of a large, healthy, flourishing field of cotton, he saw a small spot of rust, and he determined to surrender at discretion, if in the centre he should find poke weed. The poke was found, and he acknowledged himself a convert.

I may properly close what I have said of red rust, by stating, as a corollary, that though we do not know what produces it in poke or cotton, nevertheless, if poke, briars, &c., are more liable to the disease than cotton, and can communicate it, it is wise not to suffer them to take root in our fields. We know not the cause of the origin of yellow fever or small-pox, yet we know that they are communicable and infectious, and avoid persons and places suspected of being tainted with their influence.

Of the French or brown rust, though I suffer from its effects, I have very little to say. Some people have attributed it to the presence of iron in the soil, in some one of its chemical forms. Others (and I among them,) believe that it is caused by an undue proportion of lime in the soil, causing the plant to scald under the superadded influences of heat and water. I once saw the late Dr. James Davis, of Columbia, analyze soil taken indiscriminately from the land that is liable to the French, and the result was 7½ per cent of carb. of lime. Now, this is certainly a much stronger proportion than even 300 bushels of rich marl would give uniformly to the whole mass of an acre of soil, if thoroughly amalgamated with it. The flat creek lands, upon which this disease prevails, are not the alluvial bottoms; these are of a distinct character from the former, which lie between them and the sandy ridge.

I have found that late plowing promotes the French, and that compost manure is the best preventive.

Yours, very respectfully,

FARMINGTON.

From the Southern Planter.

PROPER DISPOSITION OF FARMING CAPITAL.

Mr. Editor—Every man in this country is more or less interested in the pursuit of agriculture; and the business of a commission merchant has rendered me as deeply sensitive to its interests as if I were directly engaged in its pursuit. After much consideration and attention, I am inclined to think that the want of success in this profession, proceeds from an error that I have frequently observed in my own. This consists in an attempt to do a larger business than is justified by the quantity of capital employed. It is true, that sometimes a "lucky hit" in trade will make all right, but ninety-nine times out of a hundred, failure is the inevitable result of an expansion disproportionate to the quantity of capital to be commanded.

How often do you see an individual with a limited capital embarking in the profession of a farmer, expend it all in the purchase of his land; which is about as reasonable as it would be in a merchant to sink his whole capital in a warehouse, without leaving any for the purchase of goods. Neither the one nor the other would be wiser than the silly fellow, who expended his last cent in the purchase of a purse.

I have grown grey in the pursuit of commerce, and it may be deemed presumptuous in an individual engaged in one pursuit to pretend to advise those in another calling, but the looker on can sometimes see what escapes the attention of the player, and for the last forty years I have been a not inattentive or uninterested spectator of the progress of an art on which my own pursuits were founded, and with which they were so intimately blended. It seems to me, then, nothing would more promote the cause of agriculture than a judicious division of the capital embarked in it. To make this division constitutes a rather difficult sum in arithmetic, one of the quantities only being known, but a practical man with a little calculation, can readily approximate it without even a recourse to algebraical signs. Suppose an individual desires to engage in farming, and that he has, we will say, ten thousand dollars to embark in the business. The first object is to ascertain how much land he should buy. Let him remember that it is only a certain degree of fertility that will pay for cultivation, and that within reasonable limits, the greater the fertility the greater will be the profit upon the investment. My advice to him would be to be satisfied with nothing that would not yield eight barrels of corn and twenty bushels of wheat, at least, to the acre. We will suppose that such land in the location he chooses will cost forty dollars an acre: very well, let him reserve four thousand dollars to purchase negroes, stock, implements, &c., and to afford him floating capital for at least one year's operations: this leaves him six thousand dollars for the purchase of one hundred and fifty acres of land. It is a small farm, it is true, and the owner could not be esteemed a great landed proprietor; but it is well stocked, well provided, very productive, and the owner with every thing well fixed and comfortable, free from debt and with a provision for accidents, is enabled to devote his whole energies to his business. How certain in such a case would be the annual improvement of his land, or the annual extension of his acres.

But let us contrast with this operation the course usually pursued by those investing in real estate. From an inordinate desire that seems to be born with us here in the South, to be the owners of "broad acres," the whole capital is expended in an extensive and barren waste, or probably half the purchase money paid, and a debt incurred for the balance. Little or nothing left for stock or implements, which are probably bought on credit, and are frequently of the rudest and poorest kind. Already saddled with a heavy debt, the interest on which begins to stare him in the face and haunt his imagination in his dreams, what does it avail to tell this poor wight of some improved implement of agriculture, or of a judicious system of husbandry? Why, if you advise him to pay a dollar a year or an agricultural newspaper, he replies, and with a great deal of truth indeed, that "he can't afford it." There is a perpetual struggle upon the part of this great *land owner* to keep body and soul together, and instead of ease, thrift, and improvement, he exhibits from year to year the increasing marks of care, poverty and want; until at last his great estate slips through his fingers and falls into the possession of some individual, perhaps, who having the means of improvement, doubles or quadruples the product, and thereby makes the whole an excellent investment.

It may be said that land worth forty dollars cannot always be found in situations to which particular circumstances may confine an individual. Let the purchaser then give ten dollars an acre for one hundred and fifty acres, and reserve the balance of the six thousand dollars for improving it; he must be very unfortunate indeed if he does not succeed in a few years in bringing it up to the forty dollar standard. What I mean to maintain is, that it would form a much more profitable investment, generally speaking, to buy one hundred and fifty acres of such land for fifteen hundred dollars, keeping thirty-five hundred dollars to improve it, than to pay the whole six thousand dollars for six hundred acres.

I have been led into these considerations by conversations which I have held with many of our farmers, who, apart from this common error into which they have fallen, are sound and judicious men. I have found universally a much greater want of ability, than of desire, to improve. I say ability to improve, because I believe the improvement of poor land without money is a very slow business; to a man in debt, it is unattainable.

There are in Virginia a great many rich men owning extensive tracts of land that yield them little or no revenue. Suppose such an one would lay off a tract into farms of one hundred and fifty acres; erect neat, cheap and convenient buildings, and offer them for rent on long leases, to substantial, moral men, to be cultivated upon particular systems, prescribed by the landlord.

By the purchase of a few good negro mechanics, the buildings could be erected very economically, the material being generally to be found on the spot, and it seems to me that tenants could be readily obtained on terms that would make the investment an excellent one.—Fifteen hundred acres so disposed of, might, by judicious restrictions in the leases, be converted into a splendid estate in twenty years. If it only paid six per cent on the improvements in the meantime, it would constitute a safe and capital investment. There are many good and substantial men in the country, who have capital enough to farm it advantageously, if they could only rent good land on fair terms, who are sure to fall through when they attempt, with their limited means, to purchase for themselves.

If these suggestions should excite the attention of those much better qualified to discuss all the questions appertaining to the art of agriculture, than one who has never been connected, except incidentally, with its pursuits, my object will have been attained.

Your obedient servant,

A Merchant.

Important to Ladies.—An English paper has the following card to all fair lovers of worsted work:—

"Half a pound of soft soap, half a pound of honey, one pint of English gin, mix all well together, and, with a sponge, clean the work with it, and then apply cold water in the same manner; dry with linen—the brightest colors will be uninjured."

☞Corns may be cured by binding them tight at night with a piece of spunge moistened in a solution of pearl ash. The corn may be brushed off in the morning, having been dissolved by the action of the caustic.

From the Baltimore American.

Messrs. Editors—The diffusion of intelligence on agriculture being one of the characteristics of your widely circulated and very valuable paper, as well as to convey the earliest commercial intelligence, has induced me to give to the farmer a few practical hints on seed wheat, and its preparation, as well as on the proper time for seeding, as elicited by a late article in your paper on the subject of preparing the seed to avoid smut. It has been abundantly proven in the western counties of this State, prepare the smut seed wheat as you may, that you seldom if ever fail to produce smut wheat.—The cause is the strong infection of the smut adhering to the sound grain; not that the smut vegetates: this is by no means the fact. It is only accounted for on the principle of poison being communicated in the animal creation, which applies with equal force to the vegetable kingdom. Aided by some practical knowledge, and a desire to give all the information possible on the subject of farming generally, I have been unremitting in my efforts to obtain from practical sources in this country and Europe all that is desirable on the subject.

It is a constant practice among the most successful farmers to change their seed frequently, say once in two or three years, taking care to obtain it from a different soil. The object attained by this is to retain the quality of the wheat.

Very few American Farmers, or rather wheat growers, are willing to apply the labor necessary to prepare the seed for sowing. This with the English, Irish and Scotch farmers, has become indispensable; their constant practice is to purify the seed by passing it through a strong brine, then roll it in slacked lime similar to rolling it in plaster; the safest way is not to let it lay in the brine more than one or two hours.—By this process, if the argument holds good that from impurities in the wheat smut proceeds, and the egg producing the fly is deposited on the grain, the cause for these will be all removed; you will have at least accomplished one grand object by the cleansing and rolling—the starting of the plant from the root a vigorous growth, which will go far to mature it early, and will be a preventive from fly and smut.

There is such a diversity of opinion as to the time of sowing wheat, that it is difficult to combat the different opinions. The object of fall sowing is evidently to give strength to the plant, so that on the opening of vegetation in the spring, the plant will take an early start. Early maturity of course follows, which at all times insures you a good crop of heavy wheat, provided the land is in good plight.

Having the fly to contend with in the autumn, at which time it is most destructive to the growing wheat, you will hardly take the risk of sowing too early, and if too late, the weak state of the plant in the spring will cause you to have the fly to contend with. Then taking the middle course of time is by all means the safest, say from the 1st to the 8th of October. By this time you will have had frosts that will be destructive to the insect, if on the surface. If attacked from the root, its progress will be retarded for want of heat.

It will not have escaped the recollection of the wheat grower in 1836, I think, when there was a total failure of the wheat crop in nearly all this country, then it was owing to early sowing, which luxuriated fairly, but was all cut down by the fly in the autumn. J. Meixsel.

Baltimore.

To Dry Cows intended for Fattening.—Take an ounce of powdered alum, boil it in two quarts of milk till it turns to whey; then boil in this whey a large handful of sage, till it is reduced to one quart; rub the cow's udder with a little of it, and give her the rest to drink. First milk her clean, and afterwards draw a little milk every second day, lest the udder become over charged. Repeat the dose and operation if necessary.—*Monk's Agr. Dictionary.*

From the Central New York Farmer.

CATTLE SHOW AND FAIR OF THE N. Y. STATE AGRICULTURAL SOCIETY.

ROCHESTER, September 19th, 1843.

We arrived in Rochester on Monday, and found her citizens spiritedly engaged in making the necessary arrangements for the Fair, which is to be held here to-morrow and next day, (Wednesday and Thursday,) and which promises to be one of the most brilliant exhibitions of the kind, which has ever been witnessed in the State. We intend to give a full report of the proceedings, and for the purpose of laying it before the readers of the Farmer at the earliest possible time, shall give the doings of each day separately, and forward to the Printer, so that the paper may be issued immediately after the close of the exhibition. To-day (Tuesday) has been devoted entirely to the reception and arrangement of articles for exhibition. Although many articles will doubtless be brought on to-morrow, there are enough already presented, to make the exhibition entirely creditable to the Society and to the farmers of New York. Of Ploughs there is a great variety and from every part of the State. We have noticed those from Mr. Chase, of Amsterdam, Mr. Avery, of Oxford, Tefft, of Amherst, Erie Co., Stanford and others, of Rochester, Miner, of Peekskill, Delano, of Mottville, Madison Co., Davis, of Waterloo, Bostwick, of New York, Burrall, of Geneva, Vanbrocken, of Niagara Co., and Hall, of Pennsylvania. Mr. Wilson, of Vernon, Oneida Co., has also arrived with a plough which is not yet on the ground. In this department there is a deep interest, and the manufacturers look for a fair and full trial. Of other implements there is a pretty good exhibition—such as Threshing Machines, Cultivators, Seed Sowers, Horse Rakes; and Mr. Burrall, of Geneva, has brought on a Clover Mill, which is, we believe, the only one on the ground. Last year, the exhibition of Straw Cutters was very great; but we have, to-day, seen only one on the ground, and that made in this city. In the line of domestic articles, we should judge, from the entries made, that the show would be respectable, while in fruits and flowers, it will fall far short of the last year's exhibition at Albany. A great proportion of the counties are represented by productions of female skill and industry, and many of the ladies have come on in person, to attend the Fair. Of stock, although many animals are entered, more will be brought on to-morrow morning, and although the show will not be large, yet Western New York will show some fine animals. There will be no animals from the counties east of Oneida, except a Bull from the herd of Mr. Crosby, of Albany Co.—In this we are disappointed, and can hardly excuse the breeders in the River Counties for neglecting to contribute something to the show.

The Show Yard is well fitted up, on a piece of dry ground about a mile from the city, and fenced so as to prevent ingress and egress, except at the gates. The arrangement of the pens, &c., is nearly the same as last year. The city is already full to overflowing, so that persons who arrived this evening, find considerable difficulty in obtaining rooms. What will be done with those who arrive to-morrow, we know not, but the citizens and Committee of Arrangements are making every exertion to accommodate all who may arrive. The train of cars from the west came crowded, while two heavy trains came from the east this evening—and yet of those who will be in attendance, not one half are yet here. To-morrow will show a greater number of persons than ever before collected in this beautiful city. The firm and tried friends of the Society are here—such men as Messrs. Wadsworth, Tucker, Van Bergen, Doct. Beekman, Sacket, Randall, and a host of others, whose names we might mention. From other States, are Mr. Jewet, of Vermont, Mr Ferguson, and other gentlemen, from Canada, &c.—Mr. Van Buren and Gov. Bouck came in the evening cars.

WEDNESDAY, September 20.

This has been one of the most interesting and brilliant days ever witnessed in New York.—The collection of strangers is estimated at full twenty thousand, and equals, if it does not exceed the attendance last year at Albany. A great number have arrived from different parts of the Union, among whom we notice Messrs. Merriam and Phelps, and several other gentlemen from Boston, Mr. Kirkland, Secretary of Hampshire, Franklin and Hampden Society in Massachusetts, besides several distinguished individuals, residents of our own State. Early in the morning, the foot and carriage way in every part of the city, were crowded, and before nine o'clock, State st., from Buffalo st., to the Show ground, a distance of more than a mile, presented one continued mass of persons crowding their way to the yard. The rush at the gates was so great as to prevent our entrance for a short time, and when we found ourselves inside the gates, the whole field of twelve acres was crowded with spectators. The interest does not seem to have abated in the least during the day, and all seemed highly delighted with the exhibition. Of stock the number was very great, and among them some splendid animals, although in point of quality, it is doubted whether this would compare with last year's show.—Messrs. Sherwood, Wadsworth, Remsen, Alexander, Allen, &c., are here with considerable herds, and a great number of individuals with one or more animals. The show of horses is decidedly superior to either of the previous ones, both in value and numbers, and we think in this respect, Western New York has done herself great credit. Of sheep, we saw but few in the pens, but these were of all breeds, and among them some fat sheep very superior. Mr. Frisbie, of Vernon, in our county, has some fine Saxons, although they have suffered much from the journey. We had supposed that among the many fine things of which Western New York boast, she must be famous for pigs, but to our astonishment, but very few of them have condescended to pay their respects to the citizens of Rochester, at this time. Some of these, however, are fine pigs and seemed to enjoy the occasion better than the gentlemen who had called to make their acquaintance, for most of them were quietly enjoying their repose, from which they were only aroused by a thump from the cane or foot of some member of the committee. If the admirers of beauty in swine will attend the Oneida County Fair, we will show them an exhibition far greater than that at the State Fair. The mechanics have, however, done themselves full justice, by bringing a great variety of implements of almost every description, and some of them got up in a superior style of workmanship. We thought the articles entered yesterday, were very numerous, but more have been brought on to-day, making a very great variety in all. Ploughs, Straw Cutters, Fanning Mills, Threshing Machines, Smut Machines, Harrows, Cultivators, with all the various articles used on the farm, and in the garden, are exhibited in great numbers. The Ladies on this occasion, as on all others of a public nature, have done their full share to interest the thousands of spectators. Almost every variety of articles of Ladies' manufacture, was presented, but we had very little opportunity of examining the specimens, as we were unwilling to submit long to the *pressure* to which we were subjected in the crowd.

Fruits, flowers, and vegetables were here in considerable quantities, and some of them were fine specimens, but the drought has been so severe in this region, as to prevent full justice being done to this department. A beautiful specimen of Grapes, presented by Capt. Mervine, of Utica, attracted our attention, and did not suffer in comparison with specimens raised in this region of fruit.—On the whole, we think the show a good one, and highly creditable to the Society and to the citizens of the State. A large amount of money has been received at the gate for admittance, (one shilling each for persons not members,) and a great number have entered their names as members of the Society, so that we should judge that the treasury would hold out pretty well. Although in consequence of the great number endeavoring to gain admittance, there was some confusion at the gates; the whole day has passed off without disorder, and all seem to be highly pleased with the doings. The most amusing incident we have seen was when Mr. Van Buren attempted to view the stock. The attention of the crowd seemed to be at once directed to the Ex-President, rather than the stock, and all at once the whole army seemed to be moving in the direction in which he was going. The crowd became so great that he was compelled to leave the yard and proceed to his rooms at the Eagle. This will perhaps be attributed by some, to his great popularity, but we could not see but the Whigs were fully up to the Locofocos, in the chase after the "Farmer of Kinderhook."

The Agricultural Supper, at the Rail Road Depot, has just adjourned. This was expected to be a great affair, and if the number of persons in attendance is to be taken as the criterion, it was so. We have already bestowed commendations upon the citizens of Western New York, but we must be permitted to say that the arrangements for this great festival were badly planned, or what is worse, poorly executed. A few minutes before seven o'clock, (the hour of admittance,) a dense crowd had gathered in front of the building, composed of persons having tickets and those having none, so that during the fifteen minutes which elapsed before the doors were opened, we were crowded almost to suffocation, and it was with the greatest difficulty that an entrance was gained after the doors were opened. Had a suitable police been in attendance, order and quiet might have reigned where all was confusion and disorder.

Of the supper, we shall say nothing, as eating was not so much the object as to hear the distinguished individuals who were expected to address the farmers on so important an occasion. Just as the eating was over, the eastern train of cars came puffing into the dining room, bringing a great number of passengers, and among them, Hon. Daniel Webster. The cheering as the cars entered, was almost deafening, and it was some time before order was restored. Speeches were made by the President of the Society, Mr. Wadsworth, Mr. Van Buren, Mr. Granger, Mr. Leland, Mr. Webster, Mr. Ferguson of Canada, and others, some of which were heard, but with the cheers, breaking down of seats and tables, and the crowd to get within hearing distance, not one half of those present were able to hear even a portion of the remarks. We are aware that in the great labor attendant upon the getting up of such a supper, it is very difficult to avoid confusion, but we do insist that there is no cause for the entire want of system and of order, which characterized the occasion of which we have been speaking.—We have seen here much, very much, of which, in common with every citizen of New York, we were justly proud, but we will not attempt to conceal the deep mortification to which we were subjected on account of the very discreditable manner in which the whole affair at the Depot passed off. None would welcome more cordially than ourselves the distinguished men of this and other States, to the farmers' ever hospitable board, but we hope for the credit of the State and of her noble Agricultural Society, that such proceedings will not again be repeated.

We give a sketch of the remarks at the table. The President of the Society, Mr. Wadsworth, made a brief address, alluding to the success which had attended the efforts of the Society. In the course of his remarks, he alluded to the election of a farmer Governor for the State of New York—saying that our Society should be proud that a farmer had been found worthy of being elected. He regretted the absence of Gov. Bouck, who was prevented by indisposition from being present. Mr. Wadsworth also alluded to many distinguished men of our country,

who had retired from the toils and bustle of political life, to the quiet and peaceful pursuits of agriculture, and among others he alluded to Ex-President Van Buren, who was present at the table, as an invited guest.

Mr. Van Buren being called upon, rose and expressed his gratitude for the respect which had been shown him—first to those who did him the honor to solicit his attendance, and next to the audience, for the kind and cordial feelings which had greeted his appearance among them.

He spoke highly of the exhibition which he had witnessed during the day—and although his expectations had been highly raised, the reality far exceeded his highest anticipations.

He alluded to his own experience for the two last years, which he had devoted to the cultivation of his farm, and which had proved to him the happiest years of his life. He gave an account of his experiments upon his farm, showing that he had profited by the experience of others, as his farm, which two years since did not produce a supply for his own use, the present season yielded him a surplus of eighty tons of hay. He closed with some very appropriate remarks in addition, and was loudly cheered as he sat down.

Judge Leland, of Steuben Co., followed with a few remarks, in which he spoke much in praise of the farmer, and concluded by giving as a sentiment—*Gov. Bouck.* It is a credit to the Farmers of New York, that they have *one* among them capable of filling the distinguished office of Governor of the State.

The Hon. Francis Granger, of Canandaigua, one of the favorite sons of Western New York was then called up.

Mr. Granger rose amidst loud applause. He commenced by saying that something probably was expected of him in behalf of Western New York, but he said it could hardly be necessary—for on looking around him he saw all Western New York there. He alluded to the emotions he felt on entering the cars to find by his side the man who *raised* the *first bushel* of wheat west of Cayuga Bridge. That man was Abner Barlow, of Ontario Co., who was present. Mr. Granger paid a glowing tribute to the pioneers of Western New York, and concluded with the following sentiment:

"*The Pioneers of Western New York.*—They descended from Pisgah to enjoy the promised land."

The Hon. Daniel Webster, was then announced by the President amid the most enthusiastic plaudits.

Mr. Webster remarked that he had made a very rapid journey of hundreds of miles to meet with the farmers of Western New York. He came to offer them the congratulation of a poor farmer of New England. He had devoted all the time he could spare to the cultivation of the soil, and endeavored to make up by application, what he was unable to do by study. He spoke of Agriculture generally, and of its effects upon society, and after a few remarks in relation to Western New York, and said that he intended to carry home with him for the benefit of New England, what he should learn here. He closed amidst the renewed cheers of the audience.

Mr. Ferguson, of Canada, next followed in some very playful remarks, and concluded with giving—

"*The President of the New York State Agricultural Society.*"

Mr. Wadsworth briefly responded, and was followed by the Mayor of Rochester.

THURSDAY, Sept. 21.

Another remarkable day has passed, and we hasten to record a brief account of its doings.—The Ploughing Match, that holiday of the farmer, which is always ushered in with the most pleasing emotions, and which more than any one thing contributes to improvement in the cultivation of the soil, has this day been held.—The streets leading to the ground were thronged for hours before the time of commencing the trial, and before 11 o'clock, at least five thousand persons were assembled to witness a trial of skill by thirty-eight ploughmen, who had with a zeal truly commendable, entered the lists. The interest taken by practical farmers in this part of the proceedings, exceeds every other part of the exhibition. The work was much of it well done, but we greatly mistake the skill of Oneida plowmen, if they cannot excel any work which we have seen to-day.—Let them challenge the State next fall, and we shall see who is the best plowmen.

At three o'clock in the afternoon, an immense concourse of people, estimated at 5000 at least, assembled on the ground of exhibition, and listened to a most admirable address from J. P. Beekman, Esq., of Columbia Co., one of the Vice Presidents of the Society. As the address will soon be published, we prefer giving it to our readers as delivered, rather than mar it by any sketch of our own.

It has been announced that Mr. Webster would address the audience after Mr. Beekman's address—but the President of the Society announced that Mr. Webster was so unwell, as to be unable to appear upon the ground.—Hon Ex. Gov. Seward being on the platform, was loudly called for, and responded to the call. He said, last year, he thought the farmers of Eastern New York the most unreasonable men he had ever known—in calling upon him, at four days notice, to supply the place of the most distinguished man and ablest Statesman not only of this, but of any other country, the Hon. Daniel Webster, of Massachusetts—but he was constrained to say, that the farmers of Western New York were still more unreasonable in calling upon him, without a moment's notice, to make a sacrifice of himself, and to fill the place again designated for the same distinguished gentleman.

He alluded very happily to agriculture, its importance, its tendency to peace and quiet—and showed in a few bold sketches, the superiority of the farmer, over the men of many fields of battle and carnage.

He alluded also to our farmer Governor, of Schoharie, and rejoiced most heartily to see him upon the ground, and pledged himself to stand by him in every effort to improve and advance the agriculture of the Empire State. He also alluded to the distinguished agriculturist, the Ex President Van Buren, of Lindenwold, the Hon. Daniel Webster, of Marshfield, and the Farmer of Ashland, the Hon H. Clay, and said where such men were united, the cause must go forward and finally prevail, however they might differ as to Banks and Tariffs, and matters of that sort, which though of importance in themselves, must all of them yield to this one great object, the imgrovement of the agriculture of our country. Gov. Seward was loudly applauded at the close of his address.

The Ex. President and Gov. Bouck, were both called for, but having left the ground some time previously, they were not heard, much to the regret of the large audience assembled.

The Reports of the several Committees were then read, and the premiums awarded.

DRYING FRUITS.

As this is the season for drying fruits, particularly apples, peaches, pears, and the like, a few directions for the successful performance of this highly useful operation, may not be altogether uninteresting to some of our readers.—The perfection of the process consists in taking ripe fruit whose flavor and body have come to full maturity, and then dry it sufficiently to prevent decomposition, without injury to any of its natural qualities. Peaches are too often gathered and dried before they are ripe; because it is less troublesome, and the product is much larger; although such fruit is little better than bits of dried sole leather. In order to dry fruit successfully, it is well to know something of its chemical nature. All fruit contains water in two distinct states. In one, water forms a part of, the other it constitutes by far the larger element in its juices. A gentle heat drives off a good portion of the latter by evaporation, without affecting the former in the slightest degree. If, however, the temperature is raised above 89 or 90 degrees, the organization of the fruit undergoes a change, and we obtain a product more or less altered, according to the intensity of the heat applied. In this way dried fruit is often seriously injured. It matters not whether fruit be dried by the warmth of the sun, or by artificial heat, provided the temperature is not raised too high when artificial heat is employed. In drying plums and some other fruits whole, it is advisable to make an incision into the rind to promote evaporation. In France, very acid fruits, after they are partly dried, are put into warm weak ley, until their surface becomes wrinkled, when they are washed clean and the process of drying completed. This is done to remove the excessive acidity of cherries, plums, and other acid fruits.

To preserve apples and other fruits fresh, it is advisable to put them up in tight cases, and in some dry material that will prevent their coming in contact, which makes the pressure of their weight apply to the whole surface, instead of to the small points of contact when apples are laid one on top of another.—*Buffalo Adv.*

THINGS THAT HAVE BEEN SEEN.—A writer in the Prairie Farmer has seen some curious things. We select the following:

I have seen farmers that went to the store oftener than they went to mill.

I have seen a farmer's wife take the last twenty bushels of wheat from the granary to purchase a new dress, when her husband at the same time had an execution standing against him.

I have seen farmers that could go twenty miles to a political meeting, but would not go five to an agricultural one.

I have seen farmers that had but little except "dog fence," but I could not see that they had better crops than those that had good rail or board fence.

I have seen farmers that burned their straw when threshing their grain in the fall, and go begging the same article before spring to keep their stock alive.

I have seen a farmer that travelled one hundred and four miles in the course of a year to use his neighbors grindstone, when two days' labor would purchase one that would last ten years.

I have seen young men that could pay ten dollars for a "spree," that would not pay one dollar for the Prairie Farmer.

I have seen a mother that called her child a "brat" in the cradle, and in two years the child called her a harder name.

I have seen a farmer in Illinois that cut down thrifty saplings in his door yard, and then set out others in their place that would require ten years growth ere they would present the same beautiful appearance.

I have seen farmers that would carry their produce fifty miles to market, when they could sell it at their own doors for the same price.

I have seen many farmers that would drink slough water and have the ague six months, when four days labor would dig a good well.

I have seen farmers' daughters that were "*very accomplished*" in every thing except carding, spinning, weaving, knitting, churning, making cheese, cooking, &c.

TO PREVENT WORMS AND BUGS FROM DESTROYING CABBAGES.—Mr. William Putnam, of Methuen, tells us he soaks his cabbage seed in brimstone and soot to keep the worms from the roots. He says that he has good cabbages when others have nothing but pork for the boiler. He says any one can raise the Early York, but it requires more attention to raise the Drumhead.

He recommends coal-dust for vines of all kinds—even cinders from the forge where sea-coal is burned. He spreads his coal-dust on the ground, and he says the squash bug and the yellow bug are so much offended with such proceedings that they fly away.—*Mass. Plowman.*

PLANTERS' CALENDAR FOR SEPTEMBER, OCTOBER AND NOVEMBER

The work of each is almost the same: picking cotton, ginning, pressing and hauling, with a continuance of the same; pick cotton clean, no trash at all admissible; go in for quality, rather than quantity—one bale of finely handled cotton *may* bring you $40, but a bale of trashy, dirty, cut and twist, will not over 25 or 28.—Don't attempt to gin over two bales a day on a 50 saw gin, let your mules take a steady, slow gait; quick work suited flush times—but, earnestly, rapid motion must break the fibre and cut it; whereas slow, regular and steady motion must pull it off the seed—the gin really only draws the staple off the seed. In pressing, put in 420 to 430 pounds in a bale, run screw well home, and cover every particle of cotton, sew sides *and ends* neatly, in the press if you can; put on not less than seven ropes, eight is more common; draw rope tight with a windlass attached to press, which many have not, and tie hard, so the rope will hold bale as near size as possible.

In September or October, you would do well to stop hands enough to plow in your Egyptian oats, rye and wheat; sow of oats 1½ to 2 bushels; rye, 1½ bushels; of wheat, 2 bushels per acre; sow grass seeds either of these two months. Your grain fields should be to themselves, so as to admit pasturing down if too luxuriant.

Rather than pick cotton while wet from rain, you would do better to continue your repairs, putting down woods pastures, and such like. It is not only very troublesome to dry cotton, but the dirt and leaf becomes attached and stains the cotton; and it not unfrequently happens, quantities of cotton are kept wet by cloudy, rainy weather in September, that sprouts the seed, and injures cotton materially. A few of these wet days can be employed in housing corn, gathering peas—corn, if wet; by scattering in gin house, they will dry. Save pumpkins for winter eating and feeding.

It is rather injurious to land, or rather it takes away from land an excellent good, but if scarce of provender, cut up pea vines, let them lie one day, then throw up into small, but high, heaps for one day more, then haul up and pack away; —a layer of oats, wheat or rye straw, a layer of lime, with a little salt sprinkled over the vines, and so on; give the Madam enough of this, and I guarantee she will give you fine, rich butter and milk in quantities. If a plow or two were started, all the better, though it were the best policy to get out cotton when weather is fine and season favorable.—*Southwestern Farmer.*

A LAST WORD ON WHEAT.

Let no one henceforth assert that the wheat crop is uncertain. There are soils and latitudes better adapted to its cultivation than others, as is the case with all other crops, but it is really as certain a crop as any other. Why should it not be, since its cultivation dates back to the commencement of man's history? In England there is no uncertainty in the wheat crop, except what is occasioned by the vicissitudes of the seasons, and so it is in this country with those that pursue the English mode of cultivating it. Why did Wm. C. Williams, in this neighborhood, reap thirty bushels to the acre this year, while the wheat of the majority of Kentucky cultivators was not worth the reaping at all? *He* sowed early, at the rate of three bushels of seed to the acre, upon a rich clover-lea, plowed 8 to 10 inches deep, well harrowed and rolled, and laid off into beds of 9 feet width, with deep water furrows. *They* sowed late, a bushel to an acre, upon worn-out land, and scratched the surface with the plow; so that much of the seed did not come up, much that came up was winter-killed, and what remained in the spring was smothered by grass and weeds. Since the laws of nature are invariable—since like effects are certain to follow like causes, who can doubt that Mr. Williams will always have a good wheat crop, or that his careless fellow citizens will always have bad ones, while both pursue their respective methods? If Mr. Williams produced on 20 acres 600 bushels of wheat, he would upon 100 acres of the same sort of land, with the same sort of treatment, have produced, inevitably, 3000 bushels; and if he produced thirty bushels of wheat an acre this year, will he not, under like circumstances, gather a similar harvest next year, and the next, and the next?

Let not the farmer neglect to soak his seed in strong brine and then roll it in lime. This is always done in England. Many believe it will prevent rust, although it seems to have failed in some instances in this region. At all events the washing will get out the bad wheat, and make the seed sprout and grow off more rapidly, and the salt and lime will act as manure.

Louisville Journal.

RHUBARB.

We take this opportunity of recommending to the favorable notice of our readers this delightful vegetable, which has been too long neglected by our horticulturists and farmers. For tarts and pies, there is nothing superior to it; besides we have it at a season of the year when other substances, for that purpose, are scarce and not to be had. It is far preferable for such culinary purposes to the goose-berry or currant, and it is so prolific in its growth that a dozen, or a dozen and a half of plants is sufficient for a family. There are two kinds, one called the *giant*, the leaf stalks of which we have seen as large round as a man's wrist, but they are not so early as the common kind, nor is the flavor as delicate. In addition to their value as a dessert, they are said to have powerful medicinal qualities, particularly in those distressing affections of the bowels, which so afflict our children, and carry them off by hundreds each summer. No head of a family who regards the health of his offspring, should be without some dozen of plants in his garden.

The time of sowing the seed is in November, and the following directions for its culture, we copy from Thorburn's catalogue.

"Sow in a rich, dry, sandy loam, about three-fourths of an inch deep, as early in the spring as possible, (if done in November they will vegetate in spring with more certainty;) when the younger plants appear, keep them free from weeds; if the weather be dry, water them frequently, though with little at a time; and be very careful to protect them from the midday sun, till they get tolerably strong, for if exposed fully to it during their infant state, few will escape destruction. A wide board placed sidewise on the south side, projecting over the plants a little, will serve this purpose effectually, without depriving them of the benefit of the circulating air. The first season is their critical period; having survived that, they have nothing to fear. In November, the leaves having decayed, cover the crowns of the plants two inches deep with earth from the intervals. In April, strip off the covering till you see the tops of the plants; give all the ground a slight digging; dress it neatly, keep the beds well hoed, and always free from weeds. It is much better to propagate by slips from the old roots in the spring months. The seed start very readily if sown in the autumn, but vegetates rather slowly in the spring. The flower stalks should never be suffered to run to flower, but taken off as soon as they arise."

It is the stem of the leaf from which the tarts are made, and in taking the stalks, remove a little earth and bend down the leaf you would remove, slip it off from the crown, without breaking or using the knife. The stalks are fit to use when the leaf is half expanded; but a larger produce is obtained by letting them remain till in full expansion.

As some of our readers may not be acquainted with the manner of cooking this vegetable, we will give the following, to the goodness of which we can testify.

Wipe the stalks with a dry cloth; peel and cut them into small pieces; put them into a stew-pan, with sufficient water to cover them, and when scalding hot, drain off the water, put in sufficient sugar to sweeten, and stew them gently for a few moments; stir in some butter, and such kind of spice as is agreeable; cover the plate with paste, and put in the preparation, and cover with paste as for an apple pie, and and bake in the usual manner.

Another method is to "peel and wash one or two dozen sticks of Rhubarb; put them in a stew-pan with the peel of a lemon, a bit of cinnamon, two cloves, and as much moist sugar as will sweeten it, set it over a fire, and reduce it to a marmalade—pass it through a hair sieve, then add the peel of a lemon, and half a nutmeg grated, a quarter of a pound of good butter, and the yolks of four eggs, and one white, and mix all well together; line a pie dish that will just contain it, with a good puff paste, put the mixture in and bake half an hour.

Central N. Y. Farmer.

WATERY POTATOES.

Watery potatoes, or those in which carbon does not abound, are always deficient in nutritive qualities, which depend on the presence of carbon. The latter cannot exist in just proportion independently of proper light and heat. Hence potatoes grown in an orchard are never good; the light and oxygen which should act upon them, are intercepted by the leaves of the various fruit trees; the deleterious portion of the carbon, which the light and oxygen would have carried off, mixes with the watery particles of the vegetable, and it becomes not only deficient in nutriment, but absolutely unwholesome.

TO MAKE YEAST.

Take two middling sized boiled potatoes, mash and add a pint of boiling water and two tablespoonsful of brown sugar. One pint of hot water should be applied to every half pint of the compound. Hot water is better in warm weather. This yeast being made without flour, will keep longer, and is said to be much better than any other.

TO PRESERVE HAMS FROM FLIES.

For several years we have preserved our hams in charcoal; we lay the hams down in a barrel, pounding the charcoal, and placing it between the hams. The meat keeps entirely sweet. Flies never touch the meat.

CIRCLING.

Experience and reflection have convinced us that to circle our lands to a perfect level, is not the most advantageous way of preventing washing. It may do for light rains, but when such torrents pour down as we sometimes have, the circling on this plan is rather an injury than an improvement---every row gets full of standing water---some part of the bed will be a little lower than the balance---the water will begin to run over at that part of the bed immediately below; it soon wears through that, and thus makes a wide torrent, carrying away whole acres of the loose soil, or working out a gully not easily again filled up. A better plan, we are now convinced, is that followed in Virginia and other States, of grading the rows, not to a perfect level, but to such a slope as will pass off the water in a current sufficient to enable each row to carry off its water without overflowing, yet not so rapid as to wash. At the ends of the rows the water may be either passed through the fence, out of the field from each row separately, or collected in a ditch, and passed off together.

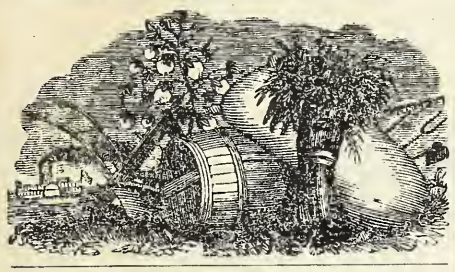
Southern Agriculturist.

ASPARAGUS BEDS.—Those who wish early and large asparagus in the Spring, will find it necessary to pay some attention to their beds in the Fall.

It is best not to permit grass or weeds to grow on the bed during the summer, but very few gardeners are careful to prevent this. It is important however, early in the Fall, to clear the bed entirely of the old asparagus, weeds, grass, &c. (Some writers recommend that these be burned as they stand on the bed,) and then cover the whole surface with a thick coat of stable or cow-

pen manure. Cotton seed is said to be still better. The winter rains passing through this coat of manure, carries much of its fertilizing properties down to the roots of the asparagus, while at the same time, it protects the bed in a great degree from cold, and thus tends to hasten forward the shoots in the Spring. Early in the Spring, this coat of manure should be carefully scraped off, and salt sown freely over the bed, say a half bushel to thirty feet square.

We have tried this method two years, and can speak confidently of its results.—*Co. Planter.*



WEDNESDAY, OCTOBER 11, 1843.

Back Numbers.—All new subscribers to the 'Southern Cultivator" can be supplied with the back numbers.

AGRICULTURAL FAIR.

With the hope that it may excite among Southern planters a spirit of emulation, we have transferred to our columns an account of the great State Agricultural Fair of New York, which we commend to the attention of our readers. We should have been pleased to have given some of the speeches of the distinguished guests, but our limits will not permit, and we must, therefore, forego that pleasure.

We have from, time to time, briefly urged upon the consideration of our readers, the importance of Agricultural Societies, and the immense benefits which they confer upon the country, both in the improvement of the system of agriculture, and the consequent increased production of labor, but we know not that we could enforce these truths by any argument so powerful, as the spirited sketch which we copy of this fair. That improvements in agriculture, like every other department of trade or business, can be advanced more rapidly by an association of men, uniting and concentrating the force and power of their intellects and experience to the attainment of the great end, it seems to our mind, is a truth so palpable as not to require argument. It is, therefore, strange, passing strange, to us, that while men unite and form associations and clubs for the accomplishment of objects of much less importance to the well being of society than the improvement in agriculture, they should seem so reluctant to enter into an association for the attainment of an object of such paramount importance to every class of society. There is, there can be, no good and sufficient reason offered for such a positive neglect of duty. It cannot be supposed, by any rational man, that the great objects of creation are answered, if we sit down quietly and attempt no improvement of the age in which we live, in whatever department it may be our lot to labor. How, then, shall we answer to ourselves, and particularly to those who come after us, if we permit, by our remissness, the important science of agriculture to retrogade, while the march of every thing else is onward? We cannot excuse ourselves for such an omission of duty—a duty alike prompted by our own interests as the high behests of creation. But we will not now enlarge upon this subject, for, as the labors of an editor have been aptly compared to a horse in a gin, we shall continue to urge it, until we succeed in arousing among our planters a spirit for improvement, or abandon the cause in hopeless despair. It is, indeed, a noble cause—one worthy to engage the highest talents in the land—and should excite to a common effort every philanthropist.

The American Agriculturist's Almanac for 1844.—We are indebted for a copy of this work, to Mr. A. B. Allen, editor of the American Agriculturist, which is thus noticed by the American Farmer:—"Besides the astronomical matter usually found in Almanacs, this contains Northern and Southern Calenders for the farmer, planter and gardener; an interesting essay on lightning rods, a cut of a permanent fixture for stacking grain, such as is used in England, and a very interesting description thereof; interesting papers on several varieties of sheep, illustrated by engravings so true to life that any one who may have seen them could identify the live animals at any distance of time; a paper on hoeing crops in dry weather, together with an account of the Dorking fowls, which is also illustrated by a very spirited cut, representing a rooster proudly strutting between a brace of hens. The work is highly creditable to the enterprise and talents of its editor; but why need we say this, having already told the reader that it is by A. B. Allen."

From the Columbia (S. C.) Planter.

Mr. Editor.—In the various essays on planting, manuring, and working short cotton, we find nothing relative to its preparation for market; to make a great many bales seems to be the great desideratum, without regard to price, except as a general market value. This is certainly wrong. The advantages of good seeds, and an improved soil, may not be of so much pecuniary importance as the manner in which cotton is machined and put up for sale. An imperfect gin, or ignorance of its operation, may diminish one's income more than "rust," or the "nocturnal gale"—may take from the energetic and persevering planter all the just reward of his extra industry, and leave him at last with not more dollars in his pocket, after his crop is sold, than his less industrious, but more careful neighbor.

The present low price of cotton is mainly owing to the quantity made. So long as the supply was limited, the speculator and manufacturer regulated the price; the one holding heavy stocks on hand, without fear of depreciation, the other "milling" it ahead of the immediate demand, certain of an ultimate sale, at a remunerating price.

It is not so now. The speculator fears the increasing production. The manufacturer, from the supply being greater than the demand for light cottoni, is forced to consume his stock in the heaviest articles. Bagging, rope, negro-cloth—all consuming pounds to the yard, instead of a *pound* making *yards*. This fact will go far towards making the quality of the staple, and its preparation for market, a matter of greater importance. The smallest possible difference in the "sample," may condemn a man's crop to be worked up in a less estimated and less priced fabric, and cause a *speculating* difference in favor of the buyer, of almost incalculable amount; and in proof of the paradox, (if so it is,) I refer you to any merchant, who will tell you that "coarse articles bear the best profit." Pray, at whose cost is the profit made? the producer, certainly, and in two ways: first, sir, to you I say, you have lost more by carelessness than you have made by hard work, and it will bear demonstration. By *hard work* you have made an addition to your crop of one hundred pounds per acre. By negligence you have lost one cent in the pound of your crop. Suppose you raise 600 lbs. per acre in the seed—

600 lbs nett (at 33 lbs. per. 100 of seeed,) 198 lbs. at 6 cents, - - -	$10 88
Not manured, 500 lbs. nett (at 33 lbs. per. 100 of seed,) 165 lbs. at 7 cents, -	11 55
In favor of carefulness, - - -	57

And, sir, when we take into consideration the time lost ginning, packing, additional expense of bagging, rope, freight, hauling, &c., the advantage in favor of the careful man over the pushing, but careless planter, is increased.

Farming, at best, is a laborious business; yet the soil, grateful for the attention paid it, *pays* well for the labor; and when every branch of farming is pushed, and carefully attended to, although the land may be poor, the owner will "do well." I read a sentiment under the signature of "Farmington," that deserves the consideration of all who have poor land, and should be well examined by those who have rich soils. He says "he has rarely seen planters improve their condition fastest on rich soils, but rather on the poor and unproductive." The observation is true, and the cause so plain, as not to need a reason. And, Mr. Editor, unless you can convince your readers that if they do not get out their cotton neat and clean, have good gins and machinery, as well as rich land, they will contrive to "live as their fathers."

At some future time, I may scribble a notion or so about the *modus operandi* of ginning, and describe the gin, and machinery to run it. With this threat, and the wish that some man may be profited by my cogitations, I remain,

Your obedient servant,

Darlington.

From the Temperance Advocate.

TOPPING COTTON.

Mr. Editor—Allow me a small place in your worthy agricultural Advocate, to submit to your readers facts, which have come under my own observation, as to the utility of topping cotton. The practice of topping cotton has been thoroughly investigated by me, and I have found that cotton topped from the first to the tenth of August, will make about one fifth more than it would if left in a natural state. It has been suggested by some of the planters to top from the twentieth to the last of July, and experiments have been made on the present growing crop as to the utility of this practice.

I have found by topping cotton it will prevent it in a great degree from shedding its offers; this I have noticed this season, as it has been very wet with us. Cotton has generally shed its offers in the fields of my neighbors who have neglected the topping of it.

Now, I would say to those planters who have not as yet adopted the plan of topping cotton, to try it for one year as an experiment, and I feel convinced they will follow it afterwards.

O Pix.

Darlington, Aug. 20, 1843.

"If common salt be put into water, when washing cabbages or greens preparatory to cooking them, the snails, slugs, worms, &c., will come out and sink to the bottom, so that they need not be boiled with the vegetables. It is impossible to wash them out, except cabbages be taken to pieces, and people generally like to have the vegetables served up whole.

THE FARMER'S LIFE.

I love the farmer's quiet life—
His peaceful home, devoid of strife,
With gay contentment bless'd.
I love the virtues of his heart,
Which peace, and joy, and love impart
Around his tranquil rest.

I love the bloomy hills and dales,
Their healthful winds, their odorous gales,
Untainted with disease:—
I love the tales, and legends old,
By white-haired sires at twilight told,
'Mid scenes of shadowy ease.

I love the labor and the toil,
Which clothe with beauty Freedom's soil,
Where tyrant never trod!
And when each task from turmoil free,
Great God, is sanctified by thee,
And consecrates the soil.

I love the scenes of social mirth,
Which brighten around his evening hearth,
With joy unmix'd, replete;—
Where friendship's smile, and love's sly leer,
Are seen thro' joy's transparent tear,
And true friends only meet.

I love whate'er the season bring—
The flowers that blush—the birds that sing—
Eve's low Eolean breeze;—
The vernal smiles—the summer's charms,—
The autumn's fruits—and winter's storms,
All charm in their degree.

HONESTY.—That "honesty is the best policy," was illustrated some years since under the following circumstances, related by the Rochester Democrat. A lad was proceeding to an uncle's to petition him for aid for his sick mother and her children, when he found a wallet containing fifty dollars. The aid was refused, and the distressed family was pinched with want. The boy revealed his fortune to his mother, but expressed a doubt about using any portion of the money. His mother confirmed his good resolution—the pocket book was advertised, and the owner found. Being a man of wealth, and uniting with that a generous heart, upon learning the condition of the family, he presented the fifty dollars to the sick woman, and took the boy into his service, and he is now one of the most successful merchants in the State of Ohio.—Honesty always brings its reward—to the mind, if not to the pocket.

SOWING WHEAT.

1. *Time of Sowing.*—Nine times out of ten wheat sown early, say by the last of September, or not later than the middle of October, is better than the late sowing. When sown early, the roots have time to grow deep into the earth, and the plants are in little or no danger of being frozen out in the winter. May wheat may be sown a little later, but other varieties sown late will not only be apt to freeze out, but ten chances to one if the rust does not destroy it before ripening.

2. *Preparation of Land.*—Clay soil, with a good coat of vegetable or animal deposits is best suited to the growth of wheat, and the land should be broken deep, then sow from a bushel to a bushel and a half to the acre, in proportion to the strength of the land, and plow it in lightly. Some good farmers finish seeding, by harrowing or brushing and rolling, but if the land is tolerably smooth, the plowing is all sufficient, and in some cases, best.

3. *Preparation of Seed.*—Wheat should be washed before sowing and all defective grains separated, and there are many solutions in which farmers recommend the wheat to be soaked to prevent smut, and other diseases, but as our experience has demonstrated nothing satisfactory on this subject, we have, at present, nothing to recommend.

Good seed, good preparation of land, strong soil, and careful putting in at the proper season, will insure a good crop—nothing else will.

Tenn. Agriculturist.

The Rev. Mr. Richardson, of Hingham, has given renewed energy to a decaying apple tree, nearly 200 years old, by raising a bank of earth, five or six feet high, around the trunk.

AUGUSTA MARKET.

Cotton—The receipts of Cotton are now getting on our usual fall scale. The accounts per the Acadia has caused a decline in prices of at least half a cent per pound on all qualities.—We quote 6½ @ 8 cents as extremes of the market.

[We refer to the quotations below for the value of the different articles of groceries required by our planters.]

Money—Central Bank notes 8 @ 10 ℔ cent discount. State 6 ℔ Bonds 72 @ 75.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, JR.,
No. 232 Broad street, Augusta, Ga.
August 30. 18-tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, JR.

BOMMER'S PATENT MANURE.

THE undersigned is the Agent of Messrs. Abbett & Co., for vending rights to individuals for making and using the above named Manure. By reference to the following advertisement of Messrs. Abbett & Co., the prices may be ascertained. All orders addressed to me, *post paid*, at Sparta, Ga., will receive prompt attention.
Aug. 30. 18-tf R. S. HARDWICK.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days.* And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent $5
Farms up to 100 acres 10
" from 100 to 200 acres 15
" " 200 to 300 " 18
" " 300 to 400 " 20
" over 400 acres in any one farm 25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.
ABBETT & CO., Baltimore,
Proprietors of the patent right for the Southern and Western States. aug 16

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., OCTOBER 25, 1843. No. 22.

PRIZE ESSAY.

THE PREPARATION AND USE OF MANURES.

BY WILLIS GAYLORD,

(Continued from page 147.)

USE OE PEAT OR SWAMP MUCK.

According to Mr. Colman, in his Fourth Report, two-thirds of the manure used on the extensive garden and farm of Mr. Cushing, near Boston, is made from meadow muck or peat. The compost, for top dressing meadow and grass lands, is made by taking the muck from the pit in August or September, where it lies to tae next year. The compost heap is then made on some convenient place, by spreading a layer of muck eight inches thick; on the muck four inches of ashes; then another layer of muck, and so on for five layers, making a pile five feet high, in the form of a ridge. This lies through the winter, is opened and mixed in the spring, and the next fall is spread on the land. The compost for plowed lands is made of two-thirds muck and one-third manure. Fresh manure, or that which has not fermented, is always used, and care is taken not to put in so much muck as to prevent the compost's heating. The fermentation of the manure decomposes the muck rapidly, and when this is done, the compost is fit for the land. Horse manure or unslacked lime, accelerates the fermentation—colder manure retards it. It is the opinion of Mr. Cushing and his gardener, that muck for mixing with cow dung, or for putting in hog styes, should be dug from the swamp six months before using, as the action of the atmosphere facilitates the change necessary. Muck, without this preparatory fermentation, they consider of little importance as a manure.

POND MUD.

Pond mud, although not as rich in vegetable matter or humus as swamp muck or peat, is still one of the most valuable of fertilizers. The quantity of earthy matters it contains, is rather an advantage than otherwise, when applied to light or sandy soils, and will rarely be found injurious on any. As a manure, the action of pond mud is more immediate than that of unfermented muck, owing to the much greater proportion of salts and silicates it contains. It is astonishing what quantities of this manure are lying worse than useless in the thousands of mill ponds in our country. In the winter of 1839-40, Mr. Whalen of Saratoga county, drew from a pond on the Kayaderosseras creek, 1,000 loads of pond muck, and put it on a field of 17 acres, soil light and sandy, or gravelly, and reduced by *skinning* until it would produce nothing but sorrel and mullein. This field, planted to corn, gave him 850 bushels. The extra product from the use of this manure, he estimated at twenty bushels per acre. In the winter of 1840-41, he took from the same pond 700 loads, and applied it to two other fields, and with similar results. Mr. Whalen has also, at different times, drawn 800 loads from an ash swale, and found it to nearly or quite equal in its effect on vegetation, the pond mud. After the corn, Mr. Whalen has uniformly grown oats; and on these worn out lands, where he formerly would have lost his seed oats, as well as the grass seeds used, he has been successful, both taking well where the mud or muck had been used. For heavy loams of clay, Mr. Whalen is of the opinion that a mixture of lime or yard manure, with the muck or mud, would be indispensable.—This mixture, the experience of Mr. Clark, of Northampton, and others, shows, is well effected by placing the muck in the cattle yards or pig styes, to be incorporated with the manures by the feet or noses of the animals, and to act as absorbents of the urine and soluble matters that are too frequently lost.

NIGHT SOIL.

Night soil, or the contents of privies, is one of the most powerful and valuable of manures; but prejudices, combined with the difficulties formerly attending its use, have prevented much attention to it in England or the United States, until within a few years. In consequence, a substance of the greatest importance to the farmer has been regarded as a nuisance, and, in the vicinity of large cities, has truly been so. Now, since science has taught the mode of preparing it for use, its use is becoming general, and its value fully appreciated. According to the analysis of manures, made by Boussingault and by Dr. Dana, there is no manure ordinarily accessible to the farmer so rich in the carbonates or salts of ammonia as this. This will be seen by comparing it with horse dung, the value of which is well understood.

	Horse Manure.	Night Soil.
Geine	27.	23.
Salts	.96	1.2
Carbonate of ammonia	3.24	15.32

HOG DUNG.

The dung of the fattening hog approaches night soil in value, more nearly than any other; indeed, Mr. Dana supposes that for all the purposes of analysis, these may be arranged under one head. In practical use, Von Thaer, on the Prussian government farm, determined by experiment its comparative value as follows: If a soil without manure, would yield three bushels of produce for one sown, manured with different substances the result was,

Without manure	3	for 1	sown.
With cow dung	7	" 1	"
With horse dung	10	" 1	"
With night soil	14	" 1	"

COMPARATIVE VALUE OF NIGHT SOIL.

In some experiments made by Arthur Young, and detailed in the Annals of Agriculture, the effect of this manure on wheat was as follows:

Simple soil, per acre		12½ bush.
Bushels of night soil	320	37½ "
" "	240	32½ "
" "	160	31½ "
Cubic y'ds of farm yard compost	60	25 "
" " " "	30	23¾ "
30 do and 1 cubic yard of chalk		25 "

Applied to potatoes, the results were not less decisive:

Simple soil produced per acre		120 bush.
Night soil, 10 wagon loads	600	"
Bones 10 "	650	"
Hog dung, 60 1 horse cart loads	480	"
Yard compost, 60 " "	300	"

POUDRETTE.

The most common method of using night soil, or at least that in which it is most portable and least offensive, is to convert it into poudrette. This is done to the best advantage in large manufactories; and hence they are usually established in the vicinity of large cities, where the original article is easily obtained. Different processes are adopted, but the most common is to slowly dry the night soil in pans, having previously mixed it with plaster or ground peat.—The object in adding plaster or peat, is to prevent the escape of ammonia, on which the value of the manure is mainly depending. The dried mass is then pulverized—is perfectly inoderous, resembles a dry brownish powder, and may be use broadcast or in drills. In Paris, a powerful manure is made, also called poudrette, by boiling the offals of the slaughter-houses into a thick soup, making this into a stiff paste by stirring in cold ashes, then drying and grinding.

URATE.

Urate is a manure formed from a compound of urine, sand and plaster of Paris. In Paris where the manufacture is most perfect the gypsum is burnt previous to using. The value of the urates, as a manure, will be better understood from the annexed table.

Water	65
Urea	5
Bone dust	5
Sal ammoniac and muriate of potash	15
Sulphate of potash	6
Carbonate of potash and ammonia	5
	100

From this, it will be seen that urate abounds in those substances most necessary to give fertility to soils. Dr. Dana remarks that a cord of loam, saturated with urine, is equal to a cord of the best rotted dung; and in some experiments made by the French Royal Society of Agriculture, which may be found detailed in the *Dictionaire d' Agriculture Pratique, Paris*, 1828, for the purpose of comparing it with night soil, pigeon's dung, &c., known to be very effective, the result was in favor of the urate. When mixed with dried night soil or poudrette, its effect on various crops was very great. From the experiments there instituted, it appeared that urate alone acted most favorably in moist seasons. It must be remembered, however, that night soil, when properly prepared, retains all the urine, or rather its fertilizing qualities; and the fact that urine is of itself so valuable a manure, should put the farmers on their guard against suffering it to be lost from their stables and yards, as is usually done.

USE OF NIGHT SOIL.

Where the farmer is so situated that no poudrette manufactsries are within his reach, he will find that by making it into a compost with swamp muck, ashes, peat or gypsum, he will have a manure that may be easily applied, and which will possess great fertilizing powers.—The Chinese have long been celebrated for the extensive use of night soil. Their method is to make it into cakes with a rich marl, which, when dried in the sun, constitute a regular article of traffic, almost a legal tender. The Flemings were the first of the Europeans to make a common use of night soil as a manure, and hence its name of Flemish manure. There it is applied directly, and without preparation, to any crop for which manure is wanted: and the superiority of Flemish agriculture, and the great fertility of their soils, may be, in a great mea-

sure, attributed to their careful saving and use of matters which others have been most anxious to be freed from. In Spain, the celebrated asparagus of Saragossa is grown on beds of loose gravel and sand, but a little above the flow of the tide; but these beds are heavily manured, after the cutting of the season is closed, with fresh night soil dug in, and thus their fertility is sustained, and the unrivaled character of the Saragossa asparagus maintained.

BONES.

Bones, ground or crushed, form another powertul manure; and although but little used as yet in this country, there are some indications, such as the erection of mills for crushing them, that their use will soon become extensive, and our farmers be saved the mortifying spectacle, so long witnessed here, of seeing ship loads of bones exported to Europe, used by farmers there, and returned to us in the products of the soil. Col. St. Leger of Wormsworth, was the first to introduce bone manuring into England, in 1775; but it was many years before their value was fully understood; and it was only in connection with the turnip culture, that they came into general use. The manner in which bones acts as manures, and their value, will be best seen by a statement of their constituents. The bones of the ox, according to Berzelius, contain in 100 parts:

Cartilage	33.3
Phosphate of lime	55.35
Fluate of lime	3.
Carbonate of lime	3.85
Phosphate of magnesia	2.05
Soda, with a little common salt	2.45
	100.

The analysis of Fourcroy and Vanquelin, gives:

Gelatine and oil	51.
Phosphate of lime	37.7
Carbonate of lime	10.
Phosphate of magnesia	1.3
	100.

Johnson, in his lately published work on Fertilizers, says: "Dry bones contain about two-thirds their weight of earthy matter, the other third chiefly of animal matter, resembling glue. Of the earthy matter, five sixths consists of phosphate of lime and magnesia. A ton of bone dust, contains of

Animal matter, about	746 lbs.
Phosphate of lime, &c	1,245 lbs.
Carbonate of lime, &c	249 lbs.

Bones, however, vary somewhat in their constituents, some containing more of the earthy, and others more of the animal parts; take those of the calf and the elk for examples, to which the teeth of the horse are added:

	Phos'te of lime.	Car'te of lime.	An'al matter.
Calf	54.		49.
Elk	90.	1	9
Teeth	85.5	15.5	

USE OF BONES.

It is evident then, that bones abound in matters capable of producing ammonia. Dr. Dana estimates its power in this respect to be equal to 8 or 10 times that of cow dung, while, if the salts are regarded, 100 lbs. of bones contain nearly 66 times as much as the same quantity of cow dung. Experience proves that the power of aiding crops, between dung and bones, is about in the proportion of the constituents named. It is evident that much of value of bones, as generally practiced, has but little effect in extracting the gelatine; and does not remove even all the fat or oil. Under high pressure as in Papius's digester, the separation of the animal from the earthy matter is complete. The finer bones can be crushed or ground, the better or quicker will their influence be felt; and boilers, by removing the exterior cartilage and fat, renders the crushing more perfect. It is owing to this cause, undoubtedly, that many of the English agriculturists prefer dry to fresh bones; as the dust made from the former, is more suitable for sowing or drilling with seeds, than that of the latter. Bone dust is the most efficient on light and dry soils. It has been found also very useful on limestone soils and light loams; but on heavy clay or wet soils, this manure does little or no good. Bone dust is one of the most efficient manures on clover, particularly the white clover, exceeding gypsum in its effects on this plant. This is accounted for by the fact, that white clover abounds in phosphate of lime; and the phosphates of bones supply it in abundance. Although principally employed as a manure for turnips, in consequence of their importance in a rotation of crops for the animals of the farm, particularly sheep, it is considered by many farmers quite as useful, employed as a manure for potatoes as it is for turnips. Bones are found to be more valuable, if subjected to a partial fermentation before being applied to the crops. If mixed with five or six times their weight of vegetable mold or fine rich earth, and turned over for several times for a few weeks before using, the value is much increased.—Since the general use of bones has been introduced into England, vast quantities are gathered and imported from all parts of the world. As an instance of this traffic, it may be mentioned that at Hull alone, in 1815, 8,000 tones of bones were imported; and this amount, at the same place, had increased in 1835, to 27,500 tons.

GUANO.

Guano is another manure of animal origin, which has lately been brought to notice. It is the excrement of sea birds, and the immense masses of it existing on the rocky isles of the Pacific, in the vicinity of Arica in Peru, are the accumulations of centuries. That, in this state, it differs from the newer excrements, can scarcely be questioned, as the action of the atmosphere must have produced many chemical changes during the lapse of years. Analysis shows it to consist chiefly of insoluble and soluble salts, chiefly phosphate of lime and organic matter, or salts 32 parts, and organic matter 68. A large portion of the organic matter is uric acid and ammonia; and regarded as a manure, it may be considered as a urate of ammonia. It appears as a fine brownish powder, with a strong marine or fishy smell, and gives off ammoniacal fumes when heated. Several ship loads of this manure have been carried to England; and the experiments show, what indeed the analysis would prove, that it is to be classed among the most efficient of manures. It has succeeded well, whether applied to grain, grasses, or to roots. There is no necessity of enlarging on this manure here, as it is not probable that it will ever be introduced to any extent into the United States, while we have so many easily accessible sources of fertility that have as yet hardly been touched, among us. It may be mentioned in this place, that the dung of domestic fowls is one of the most valuable of farm manures, far exceeding in power that of the hog or horse; and though not equal to guano in ammonia, probably from there not being as much animal food used in its production, still deserving more attention in this respect than it has received.

VARIOUS ANIMAL PRODUCTS.

All animal products capable of putrefaction or decomposition, can be converted into manures; fish, flesh, gristle, sinews, skin, horns, hair, wool, and indeed all animal solids or fluids are of this character. The man who allows his dead animals to putrify and waste away above ground, is guilty of great improvidence; and converts what might be made a valuable manure into a decided nuisance. A dead horse covered with earth or vegetable mold, mixed with a little lime or gypsum, will, when decayed and converted into a manure and spread on the soil, add to the value of the corn or wheat grown, not enough perhaps to buy a valuable new one, but not unfrequently more than the worth of the original animal. A more disgusting sight can scarcely be imagined, than to see the fences and trees around a farmer's yard dressed out with dead lambs or other defunct animals in the spring season. All such, should be buried at once, and thus made available in other forms.

FISH.

Of the substances named above, fish is the one most commonly used as a manure. In the vicinity of the sea, large quantities of fish are annually used in enriching the soil. This is particularly the case on Long Island and Rhode Island. They are sometimes spread broadcast on the earth and plowed in; at other times deposited in the hills of corn; sometimes spread over the meadows after the crop is mowed, and allowed to putrefy in the open air. The stench, where the putrefaction goes on in the open air, is intolerable; and can only be endured by those whose olfactories have been accustomed to the nuisance. This is a most wasteful practice, and should long ago have been abandoned.—Treated in this way, but a small part of the actual value of the fish is realized; and it is not to be wondered at, that where the methods of using this manure are so different, widely different ideas of its value should be entertained.—Fish should never be used fresh, or thrown at once upon the soil. The true way of preparing them as a manure, is to make them into compost, by placing them in layers with muck, rock weed, peat, or even common loam, to putrefy. Where the soil is heavy or inclining to clay, where the compost is to be used, common shore sand, containing as it does, large quantities of particles of carbonate of lime, will be found useful as a composting ingredient with the fish. When the fish are decayed or putrefied, the mass should be dug over, the parts thoroughly mixed, and if much ammonia or offensive gas is liberated, a covering of earth should be given, and the mass be allowed further to ferment before using. In this way, fish never fail of being a valuable manure. Rock weed, eel grass, or in short any of those vegetable or animal matters that abound on the sea shore, may be advantageously used in the preparation of these composts.

REFUSE OF FACTORIES.

There are many manufactories, particularly those of skins, furs and wool, where large quantities of manures of the most powerful kind are annually suffered to go to waste, though to a much less extent than formerly. The refuse of such establishments, now frequently considered, and justly as now treated, a nuisance, may by simple application to the soil, or still better by being made into compost, be used as the best of fertilizers. One of the best farmers and most successful breeders of our country was driven into the business of agriculture, in self defence as it were. He was an extensive manufacturer, and the difficulty of disposing of the refuse and waste of the establishment, compelled him to purchase a farm in the vicinity of the city, in enriching which, these matters have been most successfully employed. Those farmers who formerly could not be induced to receive such refuse materials as a gift, would now, after the proof they have seen of their value, be happy to purchase them at a liberal price. The furrier, the tanner, the morocco manufacturer, comb maker, &c. &c. are all dealing in materials of the utmost value, when applied to the soil as manure; and the farmer little understands his true interests, who, living in the vicinity of any of these does not avail himself of these refuse matters to the utmost extent permitted.

MANURE OF WOOL.

Perhaps there is no substance more rich in matters valuable as manures, than the washings and refuse of woolen factories. Chaptal was one of the first to call attention to this matter, and the instances he gave of their fertilizing power were of the most convincing kind. It is but very lately, however, that any attempts have been made in this country to render the refuse of our factories available. All remember, when around every factory and every clothier's shop in the country, piles of refuse wool, clippings, pickings of cards, and sweepings, accu-

mulated in masses, never thought of as of value, but considered as matter of which the owners would most happily be quit. The method of disposing of them, when they no longer could be tolerated, was to throw them into the river; to apply them to the garden or farm was not once thought of. Not long since, in one of our villages, I noticed a garden, the vegetables of which had a luxuriance forming a striking contrast to others near them, and the cause of the difference was asked. "It is all owing to the refuse of that clothier's and carder's shop," was the reply. "I saw in the Cultivator a notice of the value of such manures, and the owner of the shops gladly availed himself of my offer to remove it at my expense. I gave my garden a good dressing and as this is the second year, you may judge of the value of the manure. It is probably the last I shall obtain, however," he added, "as the mill owners, after seeing its effect on my garden, are now as anxious to save this refuse matter as they were to get rid of it." The oily or sweaty matter on unwashed wool, is a soapy substance having a base of potash, with an excess of oily matter with slight traces of the carbonate and muriate of potash, all valuable as manures; and as all are easily soluble in water, such water should never be lost. A wool merchant at Montpelier, had his washing house in the midst of a field, the greater part of which he had, by the use of this wash, with which he watered his plants, transformed into a fine garden. The experiments made by Judge Buel and by Mr. Bement, with hog's bristles and horn shavings, were conclusive as to the value of these substances for manures. In short, as all substances of this nature are nearly pure pelatine, with a slight addition of the phosphates of lime, it is evident their decay must furnish an abundant supply of ammonia to plants, and therefore render them valuable as a manure.

LIQUID MANURE.

There is but one other manure of animal orign to which it will be necessary to allude in this place, and that is urine, or as it is commonly called liquid manure. Analysis proves that this is a substance peculiarly rich in materials required by plants, and experience enforces the results of analysis; yet not one farmer in a thousand makes an effort to convert this mine of riches to any account, but the whole is most generally lost to him. Dr. Dana gives the following as the constituents of cattle urine, which may stand as the type of all others, though human urine and that of the horse differ from this in the character and quantity of some of the salts contained in them:

Water	65.
Urea	5.
Bone dust	5.
Sal ammoniac and muriate of potash	15.
Sulphate of potash	6.
Carbonate of potash and ammonia	4.
	100.

VALUE OF URINE.

Compared with cattle dung, it will be seen that while that gives only 2 lbs. of carbonate of ammonia to 100 lbs. of dung, the urine gives 5 lbs. of ammonia in its urea, and nearly three times that amount in the other ammoniacal salts. One-third of urine is composed of salts, whose action on vegetation is of the most energetic and favorable kind; and yet there are thousands who call themselves pretty good farmers, who use all reasonable precaution to preserve the solid parts of their animal manures, that have never made an effort to save that which is of far the greatest value, the liquid part. But it must not be forgotten that soils must contain decayed organic matter or humus for these salts to act upon, otherwise liquid manure or pure urine can do no good. Where the wash of the barnyard and stables is saved, the loss of a large part of the urine is prevented; but when, as is too often the case, this is wholly lost, not only is the urine thrown away, but a large part of the soluble humus of the manure accompanies it. It is an excellent plan, therefore, to have some reservoir for the reception of such liquid matters as would otherwise be lost. If this cannot be done, cover the bottom of your yards with muck, or even common loam, as this will absorb and retain much of the urine and liquid matters of the dung. Experience has demonstrated that a load of loam, saturated with urine, has a more powerful effect on vegetation, than the same quantity of best rotted stable manure. Human urine is richer in salts useful to vegetation than any other, containing, according to Dr. Thompson, in 1000 parts 42½ lbs. of salts. The slightest attention on the part of the farmer, might prevent the loss of this; and many a load of swamp muck, or loam mixed with gypsum, might, when saturated with urine, be added to his available manures. Liquid manures, or rather urine, differs much in the salts it contains, according as the food is rich or otherwise. "White turneps give a weaker urine than the Swedish, and green grass is worse than either," according to Dr. Dana. Turner and Liebig found that the urine of fattening animals is richer in salts than that of store animals. Indeed, the law so well known with regard to solids, that the richer the food the more valuable the dung, it is probable holds good in regard to the urine also.

SOOT.

Soot is a valuable manure, peculiarly rich in humus as well as salts, and in its composition more nearly allied to the solid substance of animals, than any thing else. It contains of humus or geine 30.70, of nitrogen 20, and of salts of lime 25.31 parts in 100. It also abounds in salts of soda, potash and ammonia. According to the analysis of Dr. Dana, 100 lbs. of soot contains as many of the valuable salts as a ton of cow dung, and its nitrogen, compared with manure, is as 40 to 1. The ordinary farmer can make but little use of soot, as it is not to be had in the country in any considerable quantities; but those in the vicinity of cities may avail themselves of this manure with much profit. For the gardener or the floriculturist, soot is an excellent manure; but care must be taken not to use it too freely, as we have known tender garden plants at once destroyed by too liberal applications of it, particularly in a dry state.—Mixed with water, in the proportion of six quarts of soot to one hogshead of water, it has been found a most efficacious liquid for watering plants, particularly those grown in green houses.

ASHES.

Ashes, leached or otherwise, are of great value as a fertilizer, especially when used on soils that are sandy or light. Unleached, the potash contained goes to form silicate of potash, and gives the supply of silex necessary for the stems of the grasses or corn; and leached, although the potash is the greater part of it separated, the remaining phosphates of lime and magnesia go far to restoring to the fields on which such ashes are strewn, the necessary matters of which previous cropping has deprived them. 100 parts of the ashes of the wheat grain contain 32 parts of soluble, and 44 parts of insoluble phosphates, in all 76 parts. The value of ashes abounding in the required phosphates, when used on grain lands, may be seen at once, as well as the folly of those farmers who waste or sell the ashes produced in their dwellings.

[To be continued.]

GEOLOGICAL DEFINITIONS.

The primitive earths are four; clay, sand, lime and magnesia.

Clay is called, by geologists, alumnia, alumnine, or argilaceous earth.

Sand is called silex, silicious earth, earth of flints.

Lime, as it exists in the soil, is commonly called calcareous earth. The term calcareous is not properly applied to any soil, unless it will effervesce with acids.

Each of these earths, answer a determinate and specific purpose in the economy and growth of plants, and the perfection of soil lies in a mixture of the whole.

Vegetable matter.—All vegetable substances in a decaying or rotten state.

Animal matter.—All animal substances in a putrifying state.

Organic matter.—A term applicable to both animal and vegetable substances in a putrifying state.

Vegetable mould—The earthly remains of vegetable substances which have either grown and decayed on the soil, or have been conveyed thither in the progress of cultivation.

Loam is a combination of vegetable mould with the primitive earths.

Marl is a substance consisting of lime with a small portion of clay, and sometimes of peat, with marine sand and animal remains. It is useful as manure, and is distinguished by shell, clay and stone marl.

From the American Farmer.

BOTS IN HORSES—MURRAIN IN CATTLE.

It is the duty of every person who has any experience in the treatment of diseases in that noble and useful animal, the horse, to communicate to the public.

It was my province, a few years since, to have much to do with that noble animal, and of course among the number in my possession, I would find a number that would be diseased, and very often my skill and experience would be taxed to find a remedy for some of the diseases to which they would be very often subject.

The most formidable disease to which this noble and useful animal is addicted, and there is none more alarming in its attacks, is the bots.

I had consulted the highest authorities in the veterinary art for the treatment of this disease, and faithfully used the remedies laid down, without any benefit. I was induced from interest, and also for the very high regard which that noble animal, the horse, held in my estimation, to use every expedient in my possession, to cure this formidable disease. I had another motive: I had lost several very fine horses by this disease, which induced me to use and try every experiment which my ingenuity could invent, to arrest this disease among my horses, and prevent, if possible, its recurrence among them.

I am satisfied and feel convinced that I will offer to the public an infallible remedy for the bots.

Some six years since, I purchased a very fine horse, but he had the appearance of laboring under some disease. I commenced a course of treatment, which I thought would relieve him, and which I had pursued in the treatment of some other horses which had the appearance of being diseased in a similar manner to the above mentioned horse, with decided relief; but in this case all my remedies failed of their desired effect.

I was induced to try the use of lime in the treatment of this case, as I was confident he was filled with grubs or bots, as he had discharged several. I commenced by giving a table spoonful of slacked lime three times per week, in bread mashes. After pursuing this course for near two weeks, the bots began to pass off in quantities varying from ten to twenty, which he would expel during the night, from his intestines. In the meantime his appetite began to improve; and in six weeks he was one of the finest looking geldings I ever saw. From that day to this, I have kept up the use of lime among my horses with decided benefit. As an evidence of its good effects, I have not lost a horse since I began to use it.

A large number of the bots which he would expel from his intestines, had the appearance of being dead. I was induced from this fact, to put some of them in a strong solution of lime-water; as I had frequently put them in spirits of turpentine, without producing any effect on them, but all those that I put into lime were perfectly dead in eight and forty hours.

Lime is a certain preventive in keeping cattle from taking the murrain. As an evidence

of this fact, I have used it among my cattle three times per week, mixed with salt, for three or four years. In that time I have not lost a single cow, or steer, or ox, by this disease; in the meantime, some of my neighbors have lost nearly all the cattle they owned.

I will give you a stronger case than the one above mentioned. One of my neighbors who lost all his cattle, had a neighbor living within two hundred yards of him, who had several cattle which ran daily with those that died, and his cattle all escaped. He informed me that he made it an invariable rule to give his cattle salt and lime every morning.

I have no doubt it is a sure and infallible remedy for bots in horses, and a preventive of murrain among cattle. J. W. J.

COMMUNICATIONS.

STANFORDVILLE, PUTNAM COUNTY, October 17, 1843.

Messrs. Editors—As I have seen no piece in your valuable paper on the subject of making pork, and curing and preserving bacon, I shall undertake, in this communication, to give you my practice in that branch of husbandry, and will say, in the outset, that if "A Lover of Good Ham," or any one else, has ever tasted of better ham than I can show at this time, they have ate of ham that was not preserved in a Southern climate. As to my own part, I have never seen better—not even the Baltimore and Smithfield cured hams.

On the subject of making pork, I shall have but little to say, except that hogs intended for pork, the ensuing winter, should be kept in a thriving condition, from the time they have the benefit of the harvest-fields. My practice is to keep them in growing order, and the first field of corn I gather, which is in September, I separate the hogs intended for pork, and give them the pick of the field; always having another field ready by the time they have consumed the peas, &c. on the first; in addition to this, I give them one feed of corn per day, with salt about three times a week. By the time they have had the run of all my corn and pea-fields, in this way, it will be the last of November or first of December. (I will here say that I never suffer my stock hogs to go into my pea-fields, as it ultimately proves to their injury.) I then get them in a small lot and feed them on corn to harden their fat. I now have a place for scalding, &c. put in readiness, as the hogs are by this ime fat; and by no means miss the first weather that will be safe to kill hogs after they have been in close feed a few days. And for the purpose of saving the offal, &c. well, and doing every thing in good order, I slaughter about half; always selecting the best. Then put every thing in order for the next killing, which I have done in from 10 to 15 days. By making two killings of my pork, I manage the whole business in better order than I could do if I had it all on hand at once.

If the weather is unfavorable for saving pork, I have always found it best to kill in the evening, and let the hogs hang out all night. By so doing the cutting up is performed much easier, and the pieces can be cut smooth and nice, which is very important. In this case I have the meat salted up as fast as it is cut out; but if the pork is killed in the morning, I have it cut out late in the evening, and spread on the smoke-house floor, on boards, for the night, and sprinkle a little salt over it, to draw out the bloody water, and early the next morning I have it all taken up and salted well; first trimming every piece smooth and nice, by taking off the little fragments, &c., and am sure to have more salt put on than the meat will take in—then I know there is no lack for salt. In cutting out my pork, I make but six pieces of a hog after the head is taken off, viz: two hams, two shoulders, and two sides, and do not take the ribs from the side pieces, as doing so is an injury to the balance by giving it a chance to rust where the ribs come from.

In salting, I use about half a pound of saltpetre to a 1000 lbs pork, (only on the hams and jowls from 1000 lbs.) and I always use hogsheads to salt the hams in. If I have not hogsheads enough to hold all my pork, I use boxes for the sides; but have always found meat to do better to lie in the brine than to have the brine drip from it. It depends on the weather as to the length of time I let pork lie in brine. In common weather four weeks is enough, if it be very cold five weeks is best, if it be a warm time, three weeks will do. To make good bacon, pork should be killed early enough to go through the salting process by the first of January, by which time it should be hung up to cure. I salt my meat in one house and cure it in another. The only particular advantage that I know of in this is, that the first killing of pork can be curing while the other is in salt. My meat being hung up, (for this a dry, windy time is best,) after the first day I have a smoke under it every day, (except it be a very dry, windy time,) till it is thoroughly cured, which will be by the last of February; about which time, and that the dryest day we can get, we have as much of it taken down as we wish, and have plenty of good hickory ashes sprinkled on the flesh side of each piece, and have as many shelves, at a convenient height round the smoke-house, as are wanting to lay up each piece of bacon, side by side, with the skin side down. There is nothing more to be done till this bacon is wanted for use, except about mid-summer it may be examined to see if any worms have collected under it; if so, they must be killed. As to skippers, they have not been known in our bacon for years. The bacon we leave hanging we have smoked occasionally with very fine chips, and sprinkle a small quantity of ground sulphur over each parcel of chips. This will clean out the flies, &c.

If any one of your readers should object to the use of ashes on bacon, as it is hard to clean off, I would advise them to put their bacon down in salt or charcoal, either of which is, perhaps, preferable to ashes; but in the use of either boxes must be used instead of shelves. I should have used salt long before now to keep bacon in, but never can have it ready for the purpose.

I must now say something about the smoke-house, as with a shackling, open house, I consider it almost impossible to make and save good bacon. To all others I prefer a framed one, closely weatherboarded, well shingled, and so close in every particular, that a fly cannot find its way in when the door is shut. My own is pretty much of this order, and is rat-proof To make a smoke-house rat-proof is very important, as rats are very destructive in a meat house, and the object is easily accomplished and the building costs but a trifle more. It is done by having two sets of sills, and letting one set in the ground, and placing the other set, with which the house is framed, on the set that is let in the ground, then weatherboard from the upper edge of the lower sills; ram the dirt well to the outside, and drive thin heart plank and confine to the sills on the inside, taking care to ram the dirt well round the inside, and if the door and weatherboarding be well done, and the roof be tight as it should be, I will warant that a rat never gets in before the shingles rot so that he can cut them.

Allow me, in conclusion, to inform your correspondent A. B. L., of Newnan, that I shall comply, in a short time, with his request, and give him my method of ditching hill sides.

Yours, respectfully,

JOHN FARRAR.

BIBB COUNTY, September 29, 1843.

Gentlemen—If there is any thing desirable in life, it is to improve in every thing that is beneficial to, or that tends to better the condition of mankind. The man who takes no interest in the great improvements that are, and have been, going on for a series of years, must be a strange being. In the last fifty years, the farmers and mechanics have carried their improvements to an extent alike honorable to themselves and beneficial to mankind. I am now receiving a paper from Boston in less time, perhaps, than I could have received one from Savannah thirty years ago. So much for improvement and enterprize. But with such facts as this, and a thousand others of the kind, before our eyes, we find men among us that are not only idle, and doing nothing to advance this great work of improvement, but are actually doing what they can to retard its advancement. This is certainly strange. Wealth is the fruit of labor;—if, therefore, labor is properly directed, it must increase the wealth of the country. I have seen many strange things in life, but the way that agriculture, agricultural improvement, and agricultural papers are treated among us, is certainly one of the strangest things I ever saw. It is admitted that agriculture is of more importance, in a pecuniary point of view, to the people of Georgia, than any thing else, or, perhaps, than every thing else, and after all there is little done to improve it. I have long thought that one of the great causes of so much idleness and vice among us is, the slovenly manner in which agriculture is conducted among us. When a youth is called upon to display his physical powers under circumstances that promise nothing but endless labor, without either profit or pleasure, it is not strange if he becomes disgusted with such prospects, and, in the end, becomes an abandoned victim of vice—indeed, it is just what we might expect, according to the common law of cause and effect. I wish that parents

and every body else would think of this. If they wish their children to become virtuous and industrious, they must take the proper steps to produce that desirable end. Children can be made to work by a constant application of the rod, and they can be kept out of mischief by shutting them up in a closed room, but this is not the way to make them industrious or better. If we wish to make children or adults industrious, we must learn to make their business agreeable and interesting. In this way it can be done, and in no other way. Children cannot divorce themselves from the love of happiness any more than adults, and if they do not find happiness in their business, surely it is not wonderful if they look for it elsewhere. If agriculture is properly conducted, it equally delights and profits both young and old, but if it is not properly conducted, it fails to interest or reward the laborer. In view of these facts, why neglect to improve the business? Why patronise so many political papers, some of which seem to have no higher or holier object than to distract and misguide the people, and neglect the only agricultural paper in the State? Have the people made up their minds to live on politics and President making? If they have, we may look for clean teeth and light purses. The good of the country depends on the virtue and wisdom of the people more than on the President. If the people are wise and virtuous, prosperity and happiness will be our lot, let who will be President. But if the people are ignorant and vicious, no President, nor any form of government, can save us from wretchedness and ruin. We all wish, or profess to wish, for the prosperity of Georgia; but Georgia cannot be prosperous unless the proper steps are taken to make her so. If the people consume as much or more than they produce, they never will add any thing to their capital. An individual that has his head and heart trained to the dirty business of swindling, can sometimes fill his pockets by emptying those of his neighbor; but communities must get rich, if they get rich at all, by producing more than they consume. The true friends to the country are those that, by precept and example, are promoting industry, virtue, economy, enterprise and improvement, whether they understand President making or not.

We have the elements of wealth and prosperity in Georgia to a great extent, and we abound in politicians, wise men and reformers; and after all, it is said the country is in a bad condition. If this is true, if it is true that we possess the elements of wealth and prosperity, and if it is true, also, that poverty and vice abounds among us, it is because the proper steps have not been taken to produce a better state of things. I suppose we have several hundred grog shops in Georgia, and, I believe only one agricultural paper, and I fear there is no great interest taken in that. This is a strange affair. No man that thinks at all, expects any thing from these nurseries of evil but mischief, and yet we support hundreds of these dens of iniquity, that are corrupting the morals of the people and doing evil in a thousand shapes, while we are showing but little zeal to promote the great work of improvement that is going on in the world. I do not like all this. I fear it will not form a very desirable chapter in our history. I fear it may be said to old Georgia, "one thing thou lackest," and that one thing is, want of zeal in the things that promote our true interest—virtue, wisdom, industry, economy, enterprise and improvement. These things will make us get rich and happy, let who will be President.

I feel a deep interest in the "Southern Cultivator." I would rather every grog shop in the country should lack patronage and so depart, than that our Georgia agricultural paper should languish. I am sure that improvement in agriculture is among the most desirable things that could be introduced among us, and I know of no means that seem to me so likely to promote that object as agricultural papers and societies, and I earnestly recommend the people of Georgia to patronize the one liberally, and form societies in every county.

Yours, truly,

A. E. Ernest.

Covington, Newton County, October 10, 1843.

Messrs. Editors—I have but lately become a reader of your most excellent paper, the Southern Cultivator, since which I have seen several articles on preparing seed wheat to prevent the smut. I saw one in the last number, (the report of the Newberry Agricultural Society,) which comes up to my notion of the thing rather better than any I have seen, though the committee seem to speak of it with not as much confidence as I should have liked. As it is common for literary men, when they find out any thing new in science, to communicate it to each other for their benefit, why should not farmers, if they are bunglers, do likewise? There is no good reason; and as a farmer, if I may be so called, I wish to add my testimony in support of the preparation recommended in that report. I think the year 1835 was the first of my knowing any thing of soaking wheat in a solution of bluestone. The smut had become very injurious to the kind of wheat that my neighbors and myself sowed, (the red May.) My neighbor soaked, in 1835, to sow all of his crop but one acre—he sowed that with unsoaked seed. He brought the whole of it to me to thrash. I discovered some little smut in the wheat that was soaked, and I think one third of the unsoaked was smut, although sowed side by side.

The next sowing I got of my neighbor the same kind of seed, (that was, of the old wheat soaked the year before,) and prepared it myself by soaking, and have sowed the same kind ever since; and as to smut, I care not for smut mills to take it out, as there is so little it would not be worth while to be at the expense of building them. My plan of soaking is, in the first place procure good bluestone, (say of the deep color, if not, put the more in,) get a small hogshead that will hold some six or seven bushels, put in it five bushels of seed wheat, fill it up with water some four inches above the wheat, as the wheat will swell some; take three-fourths of a pound of bluestone, dissolve it in warm water, pour it in the vessel with the wheat, stir it till you think it is well mixed with the wheat; let it remain some 6 or 12 hours, owing to the weather—if warm six hours will do. When you take out your wheat, save the water you soaked the first in; add for the next five bushels one-half pound of bluestone—so for every five bushels. Lay your wheat out on a floor some five hours and it will be fit for sowing. I would recommend every farmer to sieve his wheat.

William Brown.

ON CLEARING LAND.

Messrs. Editors—Permit me, through your paper, to communicate some of my ideas to my brother farmers on clearing land—I might say experience. The plan I have tried successfully for several years, is this:—I grub, cut the firewood, and rail timber, kill the timber left standing, and split the rails in the course of the fall and winter; heaping no more brush than will give me sufficient pass-way to haul the firewood out as I need it. In that condition I let it lay one year, with the exception of shrubbing the ensuing summer, and the spring following I have a fine piece of mellow new ground, ready for inclosing and cleaning up, the standing timber all dead, the fibrous roots, the leaves and trash all rotten, and the land very often producing a double crop the first year. Nor does it stop there; for I believe the good effects may be seen for six or eight years after. Need I tell any rational man that the first year's rest is worth more in enriching the soil, when the brush and timber are lying on it, than any two or three years after it has been in cultivation? Let me invite them to look at our wood-lands, with the growth so dense that you can scarcely ride through it, the face of the earth covered two or three inches deep with leaves, and ask them to determine whether, if all be cut and burnt off the same winter, as is usually done, their land is not greatly impoverished? Need I argue with my brother farmers so plain a case? I think not; for if they will reflect one moment on the two plans, I believe they will try mine, and I venture to say if once tried they will pursue it in future.

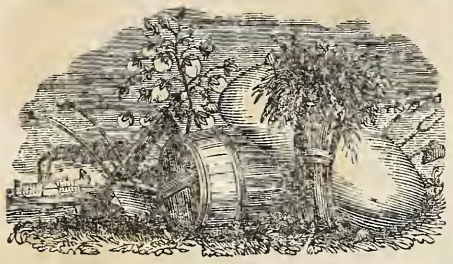
My next clearing I expect to let lay two years, with all cut and killed on it but the rail timber, and the second winter I will cut and split the rails, leaving all on the ground one year, and I expect by doing so my land will be worth more than double the same lands cleared in the usual way.

And now, Messrs. Editors, in looking over your paper, I am surprised to find so few contributing towards supporting it with their practical modes of farming. We want Georgia farming—surely no place needs improving more than middle Georgia—and I do hope that there is intelligence and patriotism enough in middle Georgia to make your paper appear what every good citizen should wish it to be.

Robert Caldwell.

Cure for Swiney.—As soon as you discover your horse is swineyed, take three ounces of rusty bacon, fry it over a slow fire until brown; take out the crackling, and, when milk warm, add the yolks of three eggs, and a table spoon-

ful of spirits of turpentine; stir all well together—apply one table spoonful to the shoulder by rubbing well, and take a piece of cloth several folds thick, lay on the affected part, and, with a hot iron, bathe the parts once each day.



WEDNESDAY, OCTOBER 25, 1843.

FATTENING PORK.

The communication of Mr. Farrar, in this number, has brought this subject to our mind, and we desire to lend our efforts to correct the great error into which many, indeed almost all, of our planters have fallen, in fattening pork. It is a common practice, we know, for our planters to turn their hogs intended for pork, into a water lot and feed them on the ground, with corn in the ear. No system could be more erroneous, whether it be considered for the excellence of the pork, or the economy in making it; both of which are considerations not to be overlooked by the prudent planter. It is well known by every planter who investigates the matter, that hogs put up and fed as we have stated, fatten slowly, and consequently consume so much food as to render the pork expensive. The reasons are obvious to any reflecting man—the food is not given to them in its most nutritious form—they eat too much dirt and drink too much water; the former of which is injurious in any quantity, however small, and the latter is only beneficial in small quantities. We might enlarge upon these reasons, but we deem it unnecessary, as every reflecting man knows, that unbroken corn does not afford the same nutrition to animals as broken; that dirt is injurious to health, and that hogs, like men, cannot eat so much when the stomach is filled with water, as when it is not. We, therefore, propose to suggest to the planters of Georgia, a plan of fattening pork, which we have tried and seen tried by others, and can consequently recommend it with the greatest confidence in its success, both for economy and making fine pork. We have no objection to the plan suggested by Mr. Farrar, of giving them the benefits of his early fresh fields, but when taken from the fields they should be put in a close pen, well exposed to the sun, large enough to hold double the number of hogs to be fattened, with good plank floor, so tight as to prevent their feet from slipping through, and a sufficient descent to admit the water to pass off, a trough extending from one end of the pen to the other, and one half of the pen (the north half) covered, to shelter them from the rain, and afford them an opportunity to bask in the sun.

Food. This should be corn meal, ground as fine as if designed for bread, made wet till about the consistency of, or a little thinner, than dough, (and if boiled it would be better,) given them three times a day, in such quantities as they will eat readily, so as never to have any food in the trough when they are fed. The proper quantity, the feeder will ascertain in a day or two. No water should ever be given them, except what is mixed with the food, and about once or twice a week, some fodder or shucks may be given them, and a little salt should be mixed with their food twice or thrice a week.

To persons who have never tried or heard of this plan of fattening hogs, it will appear very strange, but we commend it to them with every confidence that it is more economical than any other, and that the pork made by it is greatly superior to that made in the usual way.

One word as to hams. We, at the South, are too prone to regard every thing coming from abroad, the North, the far West, or any where else, which is heralded with a high sounding name, as better than any thing of home production, and hence we have heard so much about Westphalia, Baltimore, and Cincinnati cured and canvassed hams, &c. &c., that many people are almost ready to conclude that a ham made and cured at the South, is scarcely fit to be introduced on the table; particularly on any special occasion. This is all erroneous, and is to be attributed alone to the fact that we have been too little disposed, generally, to rely upon our own resources. Few, therefore, have learned that hams equal to any *in the world*, are those cured at the South, when proper attention is paid to the pork and to the curing. This is a broad assertion, but we make it with a full knowledge of its import—for we know many planters in Georgia, from whose smoke houses we can obtain hams which no Smithfield, Baltimore, Cincinnati or Westphalia hams surpass, and very few, if any, ever equal. We beg the planters of the South, therefore, to rely upon their own resources in making hams—and to the preparation suggested by our friend Farrar for putting up hams, we beg leave to suggest the mixing of 15 to 20 pounds fine brown sugar, or 1½ to 2 gallons of good molasses, to the salt for every thousand pounds hams.

Bommer Manure Method.—We have received from the proprietors, Messrs. Abbett & Co., of Baltimore, the following notice:—"Subscribers who are awaiting the appearance of the new edition of this method, are informed that it is now in press and will be out in a few days, when their orders will be immediately filled."

Consumption of Great Britain and Ireland.—It is stated that the annual consumption of the people of Great Britain for food, clothing, &c., is as follows:

Agricultural produce for food,	£295,179,000
Manufactures,	262,085,000
Imports, (raw produce,)	55,000,000
	£612,264,000

The exports from Great Britain to the whole world, for 1840, were as follows:

Total amount,	£51,406,430
To the Colonies	17,378,550
Actual foreign trade,	£34,027,880

From the S. C. Temperance Advocate.

NEWBERRY AGRICULTURAL SOCIETY.

REPORT OF THE COMMITTEE ON THE HORSE.

There is no subject amongst the animal creation, that can more justly claim the attention of every man, than that noble and useful animal, the horse. There are a great number of animals under the control of man; on reflection, we must say, that the excellent and noble horse, unquestionably, is the most serviceable. How often do we see him the sole dependence of the poor farmer and his family. Trace him in all conditions, you will find him faithful, affectionate, and no less useful. For the quick communications by posts and stages, even with the most remote parts of the Union, we are indebted in a great measure to the horse. Even our happy republican government has been established, protected, defended, by the means and aid of this noble animal. Reflect for a moment, and you cannot help but see, how battles have been won, tyrants dethroned and liberty sustained, by the aid of this noble animal. How often are we conveyed in safety at night, amidst difficulties, dangers and unfamiliar roads. View him in the service of man in every situation, when treated with humanity, and he is always ready and willing, with an aspect happy, cheerful and gay.

If, by our Report, we can aid in disseminating information to the public in the way of breeding and raising this noble animal, the horse, we think we shall have done some good. The breeding and raising of horses is both an amusing and pleasing task, and is well worth the attention of every person whose situation will admit of it. In the first place, be particular in selecting a good stock to breed from, in order to raise a beautiful and good horse. A stallion should be made choice of, that will be a good cross and of good blood; he should not be less than five feet two inches high, but five feet four inches high is a preferable size. He should be well proportioned, elegantly formed, and clear of all defects, particularly the spavin and blindness, and should be a sure foal getter.

A mare should be made choice of, not less than five feet high, five feet four inches is preferable, with a delicate head and neck, great length of body, large belly, her thighs long, large, full and bulging, her fore arm large and swelling towards her breast, hocks broad, strong and boney, legs of moderate size, thin, flat and sinewy, pasterns rather long and small than otherwise. When you commence breeding with a mare of the above description, you are almost certain of raising a valuable colt.

Indeed, there appears to be a great similarity in the blood of horses to that which exists in man, as respects their good and bad qualities, shape, &c. We find vice common throughout some families, while we see virtue reigning in others. One breed of horses, under every care and attention, will only raise you a coarse horse or pony; whilst good blooded horses show strong marks of beauty, activity and size.

When a colt is foaled early in the spring, he or she will be under every benefit that can be derived from size, strength and age; it would be advisable to put a mare to a horse at such time as would produce a colt from the 10th to the 15th of April. A mare generally goes with foal eleven months and as many days as she is years old. After your mare has been put to the horse of your choice, she should not be confined only in bad weather, during her being in foal.—Mares frequently produce colts at the age of 15 years, and sometimes 20 years of age. They are not apt to produce at the latter age.

When the mare is near foaling let her be to herself; and if early in the season, let her have a good roomy stable to foal in; in good weather, let her and her colt be turned into a lot of wheat or barley; do not let them be turned in a lot where there is green oats, it is poisonous to the colt. Wean the colt about the 15th of September, or the 1st of October, in a stable, until it is done fretting after its dam; then turn it in a lot; if you have more than one, they will do best to

gether; stable them at night, and turn them out in the day time, except in bad weather; force them all you can the first winter. After they are one year old they should not be kept so fat, nor permitted to get poor: a stud colt, which is intended to be kept as such, should be separated from other horses at 11 months or a year old, and stabled of nights; his rack and manger should be so high as to strain him a little to get food; the windows of the stables should also be high, as he will be looking out at them; by this means his shoulders will be thrown back and his withers raised. How graceful it looks for a horse's shoulders to be well thrown back, and his withers well raised.

The best plan we have found to increase a colt's quarters, enlarge his muscles, and other material parts, is to keep him in the stable frequently for several days together, which will animate him, then turn him out in a lot, and encourage him to run and exert himself all you can, as his parts will acquire size and strength in proportion to the use made of them. When a colt arrives at the age of two or two and a half years old, it is time he should be handled and taught the use of the bit. It is of great consequence he should be first gentled by a person who well understands the management of horses, to prevent bad habits; as first impressions are hardly ever entirely removed from mare or horse.

We recommend corn for colts in the winter, and oats in the summer. Colts and horses should be furnished with good stables; great attention should be paid to stables, the removal of all offensive and putrid matter, to prevent diseases, which frequently proceeds from such neglect. A log stable is preferable to any other, on account of its admitting a free circulation of air in the summer; and by the use of rough-edge plank and straw in the winter, can be made warm. The rack should be smooth, high and firmly fastened to the wall, which will prevent a horse from injuring his eyes, skinning his face, and doing himself other injury when feeding. The upright pieces in a rack should be four or four and a half inches apart, to prevent long food from being unnecessarily wasted. The halter should never be tied to the rack, (horses have been ruined by such carelessness,) but should be passed through a ring in the manger and confined to a long, smooth piece of wood, weighing about a pound. A stall should be four and a half or five feet wide, which will allow him to lie down with comfort.

Very respectfully submitted,
H. H. Kenan, Sec'y.

REPORT OF THE COMMITTEE ON COTTON.

The Committee on Cotton respectfully report, that their object is not to point out the manner of producing the greatest quantity of cotton to the hand, for that is generally too great already; but to show the easiest and most perfect manner of cultivating the plant, so as to produce the greatest quantity to a given number of acres; and as the manner of cultivation must be much influenced by the quantity of cotton planted in proportion to that of other kinds of crop, the Committee will first direct your attention to that part of the subject. They are of opinion that, in order to enable the planter to give that attention to his cotton crop which its proper cultivation requires, he should not plant more than six acres to the hand, allowing eight for corn, and fourteen for wheat and oats,—one-half for each. They are aware that some of our high-pressure planters will say that this is not enough for cotton, for some of them plant as much as 10 acres to the hand; but for those who wish fair and easy sailing six acres will be plenty. With this quantity the planter can cultivate his crop, and attend to every necessary operation of his plantation, without that hurry and pushing which is always the consequence of a large cotton crop, and which is so injurious to negroes, working stock, and even to land. The planter, by planting moderately, is enabled to drill his corn, by allowing time for hoeing it, and thereby preserves his land from washing. He has sufficient time for harvesting and sowing his small grain, which is often neglected and injured by the press of a heavy cotton crop. The quality of his cotton is also much superior, by being gathered earlier, and his negroes are saved from the horrid train of diseases and death which are produced by being exposed, in picking a large crop, to the inclemencies and rigors of the weather through the whole winter; whereas, the quantity which the committee propose can always be got out with ease, before the hardest of the winter sets in.

Having determined on the quantity, the land which is intended for cotton should be well broken up with a scooter, and if in stubble, should be turned over in the fall, or early in the winter, with a twister, so as to allow time for the decomposition of the grass and stubble, for if this is neglected, it will be impossible to get a stand; it should then be laid off in rows, three feet apart or wider, owing to the quality of the land; and if necessary to manure, the furrow should be opened out very deep, by running, if necessary, two shovel furrows in the same place, and after scattering in the manure, a bed should be thrown on it as high as possible with a twister plow, and where the ground is sideling, drawn up with a hoe, so as to prevent the water breaking over; or if too low and wet, it should be drawn up with a hoe, to prevent the cotton from drowning out. The bed should be opened very shallow, with a small scooter plow: the seed should then be strewed in very thick, from three to four bushels per acre, and then covered with a board or hoe, or if in stiff red land, by running a scooter furrow on each side of the seed, and scraping off with a board when the cotton seed begin to sprout. As soon as the cotton makes its appearance above ground, it should be sided or run round with a half shovel or twister, running the straight side next to the cotton, and lapping the dirt in the middle of the row, so as to cover the first crop of young grass; the hoes should then follow, chopping out, and leaving three and four stalks in a place, a hoe's width apart, or more, to test the quality of the land; though, on ordinary land, about five inches will be the proper distance. This working is dispensed with by many planters, but a part of the committee are satisfied from trial of its advantages; it gives the plant an earlier start, by disincumbering it of the great quantity of cotton which first comes up, and which not only causes it to die, but must check its growth if suffered to remain until the first working is gone through in the usual way, which requires double the time necessary for chopping out, a hand being able to do two tasks, or acres, per day, and then the cotton will be in a situation to wait without injury, until the second working can be given, which consists in running with the plow in the same manner as at first, and drawing a little dirt to the cotton with the hoe, and thinning it to a stand, which in all cases should be only one stalk in a place, without regard to the quality of the land or the distance of the stalks apart. For the committee are of opinion that one stalk in a place would make more than two, if there was but the one stalk in an acre. The next or third working consists in throwing out the middles which had been left in the two previous plowings, with a twister, and drawing up a hill with the hoe, after which the cotton will be in bloom; any further working with the plow is always a hazardous operation, for if plowed too deep, or too close, or too dry, it causes it to shed its squares and small bolls, which is an injury that cannot be repaired, for the bolls which are substituted for those which have fallen off will be too late to mature. The use of the scraper or eagle plow, by merely scraping off the young grass without injuring the roots of the cotton, would obviate the risk of injury from late plowing, and would be a great desideratum for laying by a cotton crop, and perhaps for other purposes—though the committee have not made sufficient trial of them to speak positively.

J. N. Herndon, Chairman.

REPORT OF THE COMMITTEE ON SAVING PORK AND CURING BACON.

Your committee, after conferring together, come to the conclusion, that it would not be any thing amiss, to give some of our experiments in fatting of hogs, before we undertake to make pork of them; therefore, about the first of October, we put them in a pea-field that there is water in; if not so, minding to give them plenty, before we turn them in the field; we give them as much corn as they will eat, and then a little every day. As soon as they have ate the peas pretty well out of that field, put them into another until we wish to pen them; we then make close pens and floor them, and put them in; we shell the corn that we give them, and soak it from 12 to 16 hours. We keep salt pretty constantly in their trough. By this plan we can fatten our hogs on a great deal less corn, than to feed it dry. We kill our hogs from the middle to the last of December, which is generally a favorable time for saving pork. The day we kill we cut up and salt lightly down upon plank, which draws out a great deal of bloody water; next day we salt it over again and pack it down in tight hogsheads, minding to have every layer of meat covered well with salt, (and when we are salting, we rub the skin well;) we let it lie in salt about six weeks, we then hang it up and smoke it with green hickory wood, until we dry it properly. In the first of March, before the Skipper Fly makes it appearance, we take down the joints, and put them down in hickory ashes, (or any other good strong ashes;) the manner that some of us perform this process, is to take a large box or hogshead, sift ashes all over the bottom till you cover it, then put down a layer of hams, so as not to touch each other, then sift in the ashes, until we have filled every crack, then we take sticks about the size of a common hoe helve, and lay across in order to keep the meat separate, and so on alternately, until we have filled our box, or put down what meat we have. By this method we can preserve hams as sound and as sweet, twelve months, as they were the day they came out of the pickle.

Some of our committee have tried rubbing the joints with ground (or pulverized) red pepper, with very good success. This is done before hanging them up. All of which is respectfully submitted.

Matthaw Hall, Chairman.

From the Southwestern Farmer.

Ingleside, Adams Co., Miss., September 11, 1843.

Gentlemen—The Farmer of the 1st instant has suggested to me a few remarks—and I have an inquiry or two to make.

What means are used to preserve corn from the attacks of weevil? I find that open cribs and close cribs; the application of abundance of salt; layers of China tree leaves and branches; and gathering and storing the corn when wet enough to undergo a pretty severe sweat, have all been tried with more or less success. I was a severe sufferer last year, and am anxious to learn of a preventive.

Is the *Thumps*, in a horse, curable or not? If curable, by what means? Is it a violent palpitation of the heart? or, what is the cause of the animal's suffering? It differs from heaves.

What is the objection, if any, to a *brick* smoke house? Is it, or is it not, preferable to a frame or log building for that purpose? I ask for information—and should like a plan of a house, method of curing and smoking included. I have some suggestions to make, but will wait for farther *light*.

I find that a good table spoonful of spirit of hartshorn, given to a horse afflicted with colic, will afford instant relief. It may be put in a bottle, and water enough added to drench with. I am indebted to a medical friend for the prescription.

Much has been written on the comparative value of cotton seed as food for stock, and as manure. It seems to me a strange question. I cannot understand what would excuse a man's

using as valuable an article of food as manure, *while he has stock to feed it to.* Its good effect upon corn is astonishing, when applied as a manure—but, if it was first *passed through the mill* by the hogs and cattle, both being kept well littered in their pens, the manure would be equally good and in greater quantity—and, in addition, a large amount of pork and beef made. I have been feeding it freely to both cows and hogs, first cooking it—and I think that I have lost several hogs by it, because the careless negro *had not cooked the seed*, but merely warmed it. If properly cooked, a little corn meal or bran added, with salt and a large shovelful of wood ashes to each kettle-full, there is no danger of injury to the stock. Uncooked, sound seed I find to be very bad for cattle, sheep and hogs. There is one lady in this vicinity, whose butter commands the highest price, at all times, in the Natchez market, who has fed cotton seed thoroughly cooked, to her cows for twenty years. Some pretend to say they can discover the taste of the seed, but I think if the ashes be added, it will puzzle them to do so. The cattle must of course have an abundance of rough food besides—and the hogs must have *rooting* or *grazing* range enough, according to their kind.

You are correct, you and your correspondents, on the value of crab grass, both for hay and pasture. I had several lots plowed up early last spring, and sowed in spring oats, which have afforded abundant pasturage all summer since the oats were taken off. But for either purpose, it is a long way behind Bermuda grass. As pasture, it is almost inexhaustible, thriving best in warm, clear weather—and will feed a greater number of animals on a given extent than any other grass I have ever seen, not excepting blue grass. Dr. P., I think, saw my neighbor Col. Knight's little volunteer meadow? No pains has been taken with it. The grass came of itself, and has been regularly and closely mowed three times each year. I determined to come to a pretty close estimate of the quantity it yields per acre, on moderately good land, and accordingly measured off one-fourth of an acre of *average crop*, where the grass is well set, just before the *second* cutting this year—the first cutting having been a heavier one. I had five cocks weighed, when *thoroughly dry*—in fact it was *sold* on the ground, and weighed to the purchaser—and the average yield *per acre* amounted to 10,200 lb., or five tons two hundred weight! The third cutting will be almost as great. What crab grass or fodder-pulling will equal this as a means of affording forage? Now, there is no mistake in the calculation. I went over the whole several times, that there might be done. Last year, Col. Knight's estimate was 6 tons per acre at a cutting. Bermuda is a close growing, fine, delicate looking grass.—When in meadow, it grows to the height of 12 to 14 inches—generally about a foot. Very frequently, when the scythe makes a cut, the grass just stands solid on the ground, as if it had been undisturbed, and has to be rolled out of the way with the foot. At one time I was afraid to introduce it on the plantations, it spreads with such rapidity, and can only be killed *by smothering*. Corn and pumpkins—oats followed by peas—or any such crop, I now find will kill it. I may add, that if any of your readers, who are subscribers to at least two agricultural papers, one of them being published in the State they reside in, have a desire to try it, I will with pleasure pack a barrel of roots and ship for them as they may direct me, if by mail, post paid. Yours, &c.

THOMAS AFFLECK.

☞ The New York Courier states that the amount of specie exported from that city to Europe this Fall is comparatively small. No silver has been shipped to England, and that taken to France will not far exceed $800,000, of which $100,000 will go by the next packet. The premium on silver has therefore declined considerably.

AUGUSTA MARKET.

Cotton—Throughout last week our market had been in a drooping state, with a downward tendency in prices. On Sunday night, however, we received Liverpool accounts to the 4th inst., per Hibernia at Boston, showing a very active demand, and very heavy sales at an advance of ⅛ to ¼d on all descriptions. This gave a new impetus to our market, and an active business has engaged dealers for the two last days, at an advance of fully ¼ to ⅜c on all descriptions. We now quote 6 @ 7½ cents as extremes—remarking that a very choice lot would command a fraction more.

Groceries, &c.—Our market is well supplied with goods, and prices range decidedly low.

Exchange continues as last reported. Central Bank money has improved, and the rate is now 6 @ 7 per cent discount. State Bonds are very firm.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, Jr.,
No. 232 Broad street, Augusta, Ga.
August 30. 18-tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, Jr.

BOMMER'S PATENT MANURE.

THE undersigned is the Agent of Messrs. Abbett & Co., for vending rights to individuals for making and using the above named Manure. By reference to the following advertisement of Messrs. Abbett & Co., the prices may be ascertained. All orders addressed to me, *post paid*, at Sparta, Ga., will receive prompt attention.
Aug. 30. 18-tf R. S. HARDWICK.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days.* And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent $6
Farms up to 100 acres 10
" from 100 to 200 acres 15
" " 200 to 300 " 18
" " 300 to 400 " 20
" over 400 acres in any one farm 25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.
ABBETT & CO., Baltimore,

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞ POST MASTERS are authorized to receive and forward money free of postage.

☞ ALL COMMUNICATIONS MUST BE POST PAID

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., NOVEMBER 8, 1843. No. 23.

INDIAN CORN.

Extracts and hints from the "Report of the Committee on Corn," appointed by the "Planters' Society of Fairfield district, South Carolina." JON. DAVIS, ESQ., *Chairman.*

"*A proper selection of seed corn*, is regarded an object of great importance; because as in the animal, so in the vegetable kingdom, "like produces like." Every species in creation (the which is procreative) may be improved in quality and fruitfulness, by a judicious choice of breeders; the converse of the proposition holding equally good. Twin corn, like the twin ewe, is most apt to produce twain.

"*The varieties of Indian Corn*, may be summed up in two general classes, viz: the gourd seed and the flint corn; the first called the gourd seed, because of its similitude in shape to the seed of the large gourd---and the flint, so named, because of its flinty hardness. Amongst these two general classes, there are varieties of color---white, yellow, purple and mixed colors---all of which may be crossed, or amalgamated, by the deposit of the farina or anther dust from the tassel of one plant, upon the ear and stalk of the other species.

"*The seed intended for planting*, should be not only of the most proplific and best species, but also well matured.

"There is no doubt that the selection of seed is a desideratum in the growing of all plants.

"A query for consideration arises--*which is the most profitable to the planter, the gourd seed or flint?* It must be admitted that the flint is the heaviest, according to measure, and contains more nutritive matter; but it is equally certain that the gourd seed will measure most from the acre, with equal advantages otherwise, and sufficient too to make up more than the loss o weight. Admitted, however, as an hypothesis, that this should not be realized, your committee on other grounds, would give the gourd seed a decided superiority.

"*It is more easily ground into meal:* thirty bushels of gourd seed would be ground with as much ease as twenty-five of the flint. It is more digestible, horses and hogs masticate it with less difficulty.

"It is observable, that the Indian corn is most peculiarly adapted to certain climates and soil: it is generally admitted, that the gourd seed corn will finally change into flint corn, if cultivated for a few years in the low country of South Carolina; and it is also admitted, that the same quality of lands will yield more corn in North Carolina or Tennessee, than in South Carolina.

"Your committee, in thus contending that the flint is a degenerate corn, would merely add, that if the grain arrives at higher perfection in some climates north of South Carolina, it would be advisable to procure seed from thence—provided the due attention had been given to its improvement.

The following plan has been advantageously pursued by the compiler and several of his friends, viz: before harvesting your crop, select from the most healthy and best bearing stalks the lowest ears, these gather with the inner husk on, or as it is called, slip shuck, which place carefully away in a safe place, until the season for planting, then take off the shuck and expose the ears (for a day or two before you shell them,) in the open air or sun, and to every three pecks of flint corn, mix one peck of the large, white grain North Carolina or Collins' corn. This will give you a cross between the flint and gourd seed, and a grain much admired by every planter who has seen it. It will degenerate every year, and finally become flint corn; to prevent which, the gourd seed should be mixed with it every other year, if it can be conveniently procured; but certainly every third year.

"*The best time for planting.*—The sooner we procure a stand, the more sure the crop, particularly in uplands. In low lands, subject to be overflowed, it will be unsafe (on account of spring freshets,) to procure an early stand. Corn planted in March, in general, has the advantages of the spring seasons and dews.—Whatever the reasoning may be, the experience of the intelligent planter will testify, that in three years out of four, March corn will produce the most abundant and perfect grained crop.

"*The late corn is liable* to run up tall and slender, bearing therefore smaller ears.. Independent of the advantage of a more abundant crop from early corn, it is an object to have the corn crop laid by soon, to enable the planter to look well to his other crops. Besides, it suits well for the pea crop.

"A third consideration is, *the composition and fertility of the soil.* If too much clay, (and if old land,) in a few days after a rain, it becomes too stiff for the plow, and too close for the roots to penetrate; if too sandy and porous, the strength of the soil quickly evaporates, leaving the roots of the corn too much exposed to the action of sun and air, in the heat of summer; if of a sandy bottom, as well as surface, the little strength of the soil both evaporates and sinks.

"It is better economy to pay soundly for a fine grit surface, and clay subsoil, (the land being level,) for ten years use, than to cultivate a stiff clay, or coarse sandy land, in corn, *free of charge.*

"A fourth consideration is, *the preparation of the ground*, and best plan of planting. All old lands are the better prepared, by being plowed and open to the winter freezes; and all plowings should be deep and close.

"In planting it may be expedient to put in seed enough to accommodate birds and squirrels, and still have a stand left; it is much better to thin out five plants, than to replant one.

"*If the stand is very bad*, it will be safer to plow up and plant over again, than to replant, unless the replanting is done in time to tassel with the first planting." NOTE.—Every planter must have observed, that in a field of corn where there are two different plantings, as soon as the first planting begins to tassel, the latter, though perhaps not as far advanced in growth as the first, also immediately begins to shoot out and tassel; no doubt it is caused by the farina or anther dust of the former falling on the stalk and leaves of the latter.—*Compiler.*

"*What is the best distance?* is the fifth interrogatory in planting corn. This must be varied in different climates and soils; not so apt to fire in cold climates, it will there warrant closer planting. On uplands, and in the hill, with one stalk, four by three feet; if two stalks, five by five feet.

"The sixth inquiry is, *the best plan of manuring corn ground.* It would be lucrative in every sense, to manure corn hills without exception, whether the lands are old or new; if new lands are manured, their productiveness is increased in the same proportion to old lands fertilized, and the planter is remunerated tenfold for his labor. To manure corn lands, open deep with the plow, (*or hoe,*) plant five grains in a hill, cover *lightly* with the hoe, (and if stable or yard manure, one handful,) follow after with a plow on each side, so as barely to make the mould or earth to meet over the manure. This will, on the whole, make a deep cover, but the manure will prevent the earth baking over the corn, so that it will still come up.

"If the manure is not thus covered, (especially cotton seed manure,) its value is lost by evaporation.

"*The plan for cultivation* is the seventh consideration. When the ground is in good order the two first plowings should be ever very deep and close. This will cause the earth to retain moisture in summer, and the roots of the corn to run deep in the outset, so as to prevent the plow from cutting them too much in the after plowings, which should be shallow.

"*In the production of corn*, let this be a rule—*deep* plowing in the *spring*, and *shallow* in the *summer.* Corn should be tended fast; that is to say, the plow should go over the ground every three (never less than four) weeks. It is in the very nature of the soil, that in its cultivation, it should be stirred often; it should be turned to the sun and atmosphere. If the ground is not *constitutionally* hard, it is never too dry to be plowed, but easily may be too wet.

"Many destroy the present crop *by one plowing where the ground is too wet;* and unless the earth *pulverises* or *crumbles* as the plow breaks up, *it is too wet.* When the ground is plowed too wet, the destructive effects are only prevented when a shower of rain falls before the sun dries the earth.

"*Two hoeings are necessary only* in a crop of corn; a light moulding after it first comes up, and a flat hill when laid by; four plowings in poor ground and three may answer in rich ground, if the corn makes with rapidity. *The last working in rich ground* should be when the corn tassels. To cut the roots when the corn is shooting, checks the growth, thereby preventing the tassel from emitting the farina, and thus impedes the fecundation in the shoot or ear.

"The eighth process of the corn crop is, *to gather the blades for fodder.* By gathering the fodder before the *milky substance* has become calcareous, many planters prevent the ears from maturing, and certainly loses much of its saccharine and oily matter. In gathering fodder, never stop for clouds; to observe them not unfrequently insures a loss of fodder.

"The ninth and last process *is gathering the corn.* Corn may be also prematurely gathered; producing, when gathered in this way, a withered and shrivelled grain; this process should never be undertaken till the stalk has become dry."

If you intend keeping your corn any length of time, let it be harvested in the slip shuck.

Holmes' South. Farm.

The celebrated vine at Cumberland Lodge in Windsor Park, (Eng.) supposed to be the largest in the world, now contains 2,350 bunches of grapes, each averaging one pound weight. Its length is 138 feet, width 16, and it extends over a space of 2,200 superficial feet. It has been planted forty years.

MANAGEMENT OF CATTLE.

Having made some remarks in the August number of the Agriculturist, in reference to the different breeds of cattle, we call the reader's attention this month to selections for particular purposes and general management.

For milkers, select as large cows as can be found possessing symmetry and neatness of head and limbs. The hair should be soft and silky to the touch, and skin loose. It is a matter of more moment, than is generally supposed, that milch cows have a pleasant temper. An ill-natured beast, *ceterus paribus*, will not give so much milk, and even what is obtained will be taken with difficulty, and without great cautiousness she will "dry up" sooner than one of moderare docility.

In the selection of a male, great size is *objectionable*. There is no a greater error with farmers than the supposition, that a large male crossed upon small cows will improve the breed fastest. There are many objections to a very large bull. They are usually coarse, and difficult to keep fat, and their offspring from small cows are generally more ill-shapen than themselves, and are uniformly meagre, raw-boned, uncomely creatures. There are substantial reasons for this result. The produce of externally large aaimals while in *utero*, are not fully nourished by small cows; there is frequent difficulty in cows being delivered of very large calves; then they always come poor, and, in the last place, they require such a quantity of nourishment, that few small dams supply their wants. The most compactly built, firmly muscled, flinty horses of the world have not been produced by large sires, but they are the produce of the little Arab, upon dams of larger size.

In breeding it is a rule, from which there is perhaps no variation, that "*the male gives form and the female size.*" Hence the conduct of the most scientific breeders of England. Their object is to find a bull rather under than over size, with full points and perfection of form; and experience teaches, that we can find at least twenty heifers of suitable dimensions for breeders where we can find one bull which should be selected. The indispensables for a good breeder are, first, let the animal be of the *deepest* milking stock; second, medium size; third, small bone; fourth, full points; fifth, glossy hair; and sixth, soft loose skin.

In Durhams, select an animal without a *black* hair or muzzle, and by all means, have him of good disposition.

The next consideration is, to manage matters so that the calves shall be dropped about the 1st of April. July is the proper month for the cows to go to the bulls.

Difficulty in Calving.—It is not at all unfrequent that cows cannot bring forth, and by neglect we have known valuable animals die in this condition. Sometimes the cow is too feeble for the laborious exertion, and again, the calf is extremely large; in either case a little gentle assistance will relieve both dam and offspring. If the feet have made their appearance, examine if the head is between the fore legs. If it is, all will go on well, but if the head is turned, take off your coat like a gentleman and christian, roll up your sleeve to your shoulder, and insert your hand, and turn the calf if necessary, or the head forward. Then take hold of the fore feet with both hands, and as the suffering dam exerts herself, pull gently, and in nine cases out of ten the cow will be delivered in less than ten minutes.

After Calving.—Let the calf suck all it will the first day, but at evening have the cow milked perfectly clean. When the calf is two or three days old, separate the dam from it, but let them together three times a day. By all means the calf should be kept fat, and when about two months old, if properly managed and taught to eat, it should be weaned. But unless the calf receive rich food at this age it will decline, and become so stinted in its growth as never to recover from it.

In winter, calves should have a shelter, and be fed carefully. The cheapest mode of rearing any animal is to keep it always in good condition; and in this no farmer can be successful without constant personal attention. Rules are too limited to make a good manager of stock; still they oftentives materially aid. Every husbandman should be one of thought, diligence and punctuality.

Attention to Milch Cows.—Any one who would conclude his cows are so superior as to give an abundance of rich milk without the requisite food and attention, will be much mistaken, and it a man of feeling, mortified at his "ill luck" from bad management.

In winter the first study should be comfortable quarters for milkers. A cow-house is indispensable to prosperous husbandry and good living. Each cow should have her stall and be taught to go to it, and stay in it, for her meal. It is not so important to feed superabundantly, as it is to give what is to be consumed regularly. Man learns by experience that his regular meals, of proper quality rather than large amount, are essential to sound health—the same holds good with all domestic animals.

Green food is very important in winter for cows. If this cannot be obtained by the way of pasturage, roots, such as potatoes, turneps, beets, &c. will answer the purpose admirably.

Cooked food is better for cows than uncooked, and less will answer a better purpose. Currying cows in winter is essential to good health, and it materially increases the quantity of milk. This may be done with very little labor twice in the day. Cows should have good hay or rough food of some kind at all times, and regular supplies of water cannot be neglected with impunity, and daily salting is just as necessary to the cow as to her master.

Milking is not the most unimportant matter. Women were not made to manage cows, and an ill-natured man should not enter a cow yard. Let an active, quick moving, attentive man, feed, milk and manage the cows. The good old Yankee plan is for the husband to *make the fire, bring the water*, and "*pale the cow.*" while the wife sweeps the house and gets the breakfast, and really we should like to see the system adopted in the Southwest.

Milking should be performed briskly. A slow, lazy person, tugging slowly at a cow's udder, puts the kind creature so much out of patience that she holds up her milk and soon becomes dry. We advise our friends to saw off the points of their cow's horns, to prevent hooking injuriously, and by a little management with cattle while young, they will become fond of their managers, and afford much pleasure to all of sound cowish refinements to attend to them.

Last, but not least, in managing cattle, is to keep the stables clean. The cleaning should be done once a day, where the cow stands up at night, and if they are in the stalls through the day, cleaning should be done morning and evening. Let each cow have a soft straw bed for lying down.

These, to some, may appear small matters, but if our readers who have not adopted this or a similar course, will try it the coming winter, and are not amply remunerated for their extra attentions, we will confess we have written to little purpose.—*Tenn. Agriculturist.*

APPLE BREAD.—A French officer has invented and practiced with great success, a method of making bread with common apples, very far supurior to potato bread. After having boiled one-third of peeled apples, he bruised them while quite warm into two-thirds of flour, including the proper quantity of yeast, kneeded the whole without water. the juice of the fruit being quite sufficient. When the mixture had acquired the consistency of paste, he put it into a vessel, in which he allowed it to rise for about twelve hours. By this process he obtained very excellent bread, full of eyes and extremely palatable and light.

EXPERIMENTS AND OBSERVATIONS ON THE PRODUCTION OF BUTTER.

At a late meeting of the Highland Agricultural Society of Scotland, a paper entitled "Experiments and Observations on the Production of Butter," by Pro essor Traill, was read by the author. These experiments were made in connection with the late Dr. Gerard, of Liverpool, who had paid much attention to the subject, and assistance was occasionally given by Dr. Bostock, now in London. The experimenters had a dairy of four, sometimes five cows at their disposal; but after numerous preliminary trials, they found that the numerical results, on the quantity of the butter obtained, were most uniform and satisfactory, when each experiment was made on a few pints only. The process could thus be carried on in glass vessels, which enabled them to observe the progress of the operation, to collect the produce more carefully, and use a more delicate balance to ascertain the weight of the butter obtained. This likewise enabled them to make the comparative experiments on the same milk on the same day, a point regarded as of essential importance, as the richness, even of the same cow's milk, is liable to vary considerably from day to day, according to the nature of her food, her health, and possibly, too, according to the state of the weather. The time which had elapsed since the last calving, was also found to have much influence on the quantity of the butter. The quantity of butter was smallest, and the proportion of cheesy matter greatest, just after calving; and generally speaking, the milk of those cows which yielded the *least* quantity, was richest in butteraceous matter.

One of the principal objects in view, was to ascertain the comparative advantages of churning:

1. Sweet cream alone.
2. Sweet milk and cream together.
3. Sour cream, or that slightly acid.
4. Sour milk and cream together.
5. Scalded cream, or what is called *clotted* cream, as practised in Devonshire.

The principal results of the experiments are the following:

1. That the addition of some cold water during churning, facilitates the process, or the separation of the butter: especially when the cream is thick and the weather hot.

2. The cream alone is more easily churned than a mixture of cream and milk.

3. The butter produced from sweet cream has the finest flavor, when fresh, and appears to keep longest without becoming rancid; but that the buttermilk so obtained is poor and small in quantity.

4. That scalding the cream according to the Devonshire method, yields the largest quantity of butter, which, if intended for immediate use, is agreeable to the palate, and readily saleable, but if intended to be salted, is more liable to acquire, by keeping, a rancid flavor.

The process of scalding is troublesome, and the milk, after the removal of the cream, is poor, and often would be unsaleable from the taste it has acquired from the heating.

5. That churning the milk and cream together, after they have become slightly acid, seems to be the most economical process on the whole; because it yields a large quantity of excellent butter, and the buttermilk is of good quality; a point of some importance, where buttermilk is largely used as an article of diet, as it is in Lancashire.

6. That the keeping of butter in a sound state, appears to depend on its being obtained as free from uncombined albumen, or caseine and water, as it can be, by means of washing and working, when taken from the churn.

The author mentioned the interesting fact that, in the course of his experiments, he found when sweet milk and cream were churned together, and though cold water was added, after an hour and a half, and then after three hours' churning, not a particle of butter was obtained.—*Plowman.*

RULES FOR IMPROVEMENT IN BREEDING STOCK.

The rules for breeding all kinds of domestic stock, whether the horse, the ox, the sheep, or the pig, are very simple; the judgment, however, required in making selections and coupling animals together, with a view of *continued improvement*, can only be acquired by persons possessing an innate talent for the thing, and long personal experience in its practice. Still, every one who is disposed may effect something, and for their guide we merely give in a few words the long adopted principles of the most eminent breeders of domestic animals.

1. When better materials do not exist, or the person wishing to make the improvements has not the means of going abroad for so doing, choose from the *best natives* at hand for this purpose.

2. But when it is possible to do so, obtain *thorough-bred* males of the proper kind from superior improved stocks, to cross on to the native females, and so continue breeding up the grade females to the thorough-bred males.

3. Be very careful in a thorough-bred stock to use no male which is not at least *equal* to the females, and if he can be found *superior*, so much the better, for this will ensure still further improvement, if possible, in the progeny.

In various communications to the agricultural journals for the past five years, we have repeatedly urged on the farmers of our country the practice of the first and second rules above; for in following them, great and decided improvements may be made at a very cheap rate. What our countrymen most fail in, except in New England, where the beautiful reds predominate, is a want of *uniformity* pervading their stocks. Animals look much better together when they match; that is, that all shall be as near alike as possible in size, in shape, in color, in their horns, and in their *general* expression. Thus formed, they reflect a beauty on each other; and although they may command no particular attention single, yet as a body they will excite respect, and if pretty good, not untrequently admiration; for they denote at least, that there is an established system in their breeding. In Europe these incongruities do not so generally prevail. In one district, the traveller observes that the animals are nearly all black, *without* horns; in another, they are uniformly the same color, *with* horns; a few miles beyond, and we find them suddenly changed to a pure red; again, they may be white; and further, they appear in mixed colors, though still preserving a uniformity, as in the case of the Italian, Swiss, Dutch, Jersey, Ayrshire, Hereford and Durham cattle.—*American Agriculturist.*

PREPARATION FOR WINTER.

With farmers it is important to have all necessary preparations for the hard weather that is approaching. It is as essential to save crops as to make them, and too often it is the case that gathering is delayed too long. Corn after maturity loses daily till housed.

Sweet potatoes should be put away before frost, and Irish potatoes are liable to injury after the cold sets in. Above all things, have preparations to shelter stock of every kind.—Milch cows cannot be kept in good condition without protection from the pelting storms, and they will not give half the milk.

An open shelter, with a southern exposure, is easily constructed and answers an admirable purpose. Sheep should have shelters where they can escape the cold rains, and lie down on dry places.

Hogs are the better to have protection from the rain. Care, however, should be taken that their sheds be kept free from wet straw, corn husks, or any thing that will induce diseases of the skin. It is important that their apartments have all the dust and litter scraped out every few days.

The secret of having stock in good condition through winter is to have them fat at the start, and then commence feeding early, and be sure that they have regular attention and are not suffered to fall off. One good animal well attended is worth more than two inferior ones neglected. A fat, strong farm horses will do more work than two feeble, poor animals. Keep no more animals than can always be in condition, is the secret of success, and it is to be regretted few adhere to this rule.—*Tenn. Agr.*

PRESERVING SWEET POTATOES.—We copy the following method of preserving potatoes from the American Agriculturists' Almanac:—

Select a dry place, level the earth, and lay a bed of dry straw so as to form a circle of about six feet in diameter. On this straw pile up the potatoes until they form a cone four or five feet high, over which spread a little dry grass. Then cover the entire cone with corn-stalks set up endwise, with the buts resting on the ground, and the tops reaching over the apex, of a sufficient thickness to conceal all of the potatoes. Then cover the whole pile with earth at a depth of at least a foot, without leaving any air-hole at the top, as is frequently done. A small shelter should then be made so as to prevent the rains from washing off the earth. This may be done by inserting in the ground about the pile four forked stakes, on which rails may be placed to support the covering, which may consist of boards, bark, thatch or other substances. Potatoes can be preserved in this manner until June, nearly as fresh as when first put up.

WILKES AGRICULTURAL SOCIETY.—The exhibition of stock by this Society last Friday, though not to be compared with similar exhibitions in other parts of the country, was yet most gratifying, as giving evidence of the increasing interest our people are taking in such matters, and we sincerely hope that these small beginnings may result in great and permanent benefits. It is by the operation of such associations that their exhausted lands are to be revived; that the disastrous spirit of emigration which has desolated this county, (called *old* Wilkes, though it has not yet been settled a century,) is to be checked; that improvements in agriculture are to be discovered and brought into use; that our people, the produce of whose labor has gone to pay strangers for their meat and bread, are to be made independent; that our citizens are to be taught to enrich and beautify the heritage of their fathers, and, by preparing for their children a home worth loving, lay the best foundation for love of country in their hearts. It is our ardent desirs to see such associations multiply and prosper, to see at least one such in every county, and every farmer a member of one.

The next Annual Fair of the Society will be on Friday before the fourth Monday in October, 1844.—*Washington News.*

SAVING SEED CORN.

Very few planters have paid that attention to the selection of seed for planting, that their own interests demand. It is a principle of vegetable as well as of animal life, that "like produces like." Every one who raises good stock, is not only aware of the truth of this, but he carries it out in his selections of animals to breed from. He selects his finest calves and pigs, and saves them from the slaughter pen, because, being well formed, large and thrifty, he believes that their offspring will possess these qualities. But although the same thing is true in the vegetable kingdom, he seldom thinks of availing himself of the advantage of a judicious selection in his seed for planting. Some few have tried it, and by care, and a judicious selection, year after year, have brought their corn to a high state of perfection; and their neighbors, seeing their success, have eagerly sought these improved seed. It would do well the first year, but after that gradually deteriorate to the common standard, and the whole thing would be pronounced a humbug. The humbug, however, was not in the original improvement, but in the subsequent neglect. The improver commenced by carefully selecting from his field those stalks that bore two fine, large ears, and laying them carefully aside for planting. The next year he selected with as much care from the product of his former selection; and by keeping up this system, reaped each year a richer harvest.—Whereas, the other, who commenced with his neighbor's fine seed, by gathering indiscriminately into his barn, and selecting his seed from the mass in the spring, would be as likely to get the ears from an inferior as from a good stalk, and thus his seed would, by a law of nature, deteriorate to the common standard.

We believe that it is perfectly practicable to have almost every stalk bearing two good ears, on land where but one would be produced according to the usual method of selecting seed. This is not a mere opinion. It has been tried repeatedly, and with enti e success, by various persons. What has been called the Dunton, the Cook, and the Williamscorn, have all owed their celebrity to the judicious selection of seed for a series of years, by the respective gentlemen whose names they bear. True, it requires some little trouble to select every year; but every planter should have enough of professional pride in improving his system of husbandry, to take the necessary trouble, especially when he is so richly repaid by an increased harvest.—*Columbia Planter.*

MANURE.—No farmer can imagine, that has not tried the experiment, what a prodigious quantity of rich, vegetable and fibrous earth may be collected from corners and by-places that lie out of the way of cultivation, and which, from their retired position, have perhaps never so much as attracted his notice. All such refuse trash, and fibrous earths and weeds, by being conveyed to his barn-yards, at intervals, during the fall and winter, and judiciously combined with its contents will be converted into a rich, fertilizing and durable manure, merely by absorbing and retaining *that excess of putrescent fluid and effluvia* which is otherwise lost by filtration and evaporation; that is, by soaking away and drying up.

TRANSPLANTATION OF ORCHARDS.—Those who have not already on their farms a good orchard, it may not be inopportune to remind, that as soon as the leaves fall, will be the proper time to plant out one, and that as the planting of an orchard is a thing which ordinarily occurs but once in a life time, that all possible pains ought to be taken both in the preparation of the ground, the selection of the trees, and the method of setting them out. The ground should be deeply plowed, and subsoiled if possible, and should be either limed, marled or ashed. None but the best fruit should be selected; pains should be taken in planting the young trees, to make the holes large, and after *covering* the roots with the earth taken out of the holes, to fill up with a mixture of the earth taken out of them and some good, rich compost, made either of mould, ashes, the scrapings of the road, or thoroughly rotted manure, and to drive a stake down by each tree, as set out, to prevent disturbance by the winds. In putting in the young trees, all ragged or broken roots should be smoothly cut off, and the remaining ones regularly spread out.—*American Farmer.*

CURE FOR SPAVIN.—A correspondent of the Albany Cultivator gives the following as a cure for bone spavin, in its first stages, if properly applied:—"Add to two table spoonsful of melted lard one of cantharides, made fine or pulverised, and a lump of corrosive sublimate, pulverised, as large as a pea—all melted up together, and applied once a day till used up, confining it to the callous. This quantity is for one leg, and may be relied on as a cure. It will make a sore, and the joint will be much weakened while applying the medicine. No need of alarm; it will all be right when healed up."

FAME.—Fame is like a shaved pig with a greased tail; and it is only after it has slipped through the hands of some thousands, that some fellow, by good luck, holds on to it.

From the Farmers' Cabinet.

TO HAVE GOOD CROPS.

Farmers are apt to place too much dependence upon manure, supposing that if they apply that in sufficient QUANTITY nothing else is required of them. This error is not, of course, of equally evil tendency to that of using no manure at all; but I was almost ready to say it was not very much less so. If the soil be not properly prepared for its reception, and if the manure be not properly *made*, *preserved* and *applied*, it will matter little whether the "manure heap" resembled a mountain or a mole-hill. But it cannot be expected that the minute details of all the practice involved in all this, can be given in the space afforded by any periodical. One great point is to cultivate no more land than you can cultivate well, both as to labor and manure. If you have more land and less money and labor, than you can use with full effect, turn a portion of land into money by selling it, and apply the proceeds to the improvement of that retained. Thus reduce the size of your farm to the capacity of your efficient forces—labor and money—instead of trying to extend your stinted forces over too wide a surface, and thus weakening them and destroying their efficiency. The second principle is, to put your soil into good condition, by *liming*, *deep plowing*, *manuring*, and correcting its proportions of clay and sand when practicable. All land, in my opinion, will be greatly benefited by the application of lime.—Some requires more, some less, to produce the same results, but all lands require it as a constituent of the soil. You will find lime most active on red lands, but it is useful on all lands. *Deep plowing* is, in my opinion, essential to successful farming. If you have a thin soil, by deep plowing, liming and manuring, you will in a very few years, secure a deep soil. Even though you do turn up a portion of blue clay with your four-horse plow, don't be frightened at the sight of it. It is better to have blue clay mixed in a *deep* soil, than a hard pan of it under a thin one. But if you find too much clay thus turned up, correct its stiffness by carting sand upon it, and mixing it with the clay. A cart load of sand is often of more value to a soil than the same quantity of manure. Reverse the process, if any portion of the land be too sandy—carry clay to it, and thus stiffen it.

The advantage of deep plowing is almost incalculable. It will ultimately make a deep soil, and a deep soil is essential to a good crop in a dry season. The roots of the plants strike deeply into it, instead of spreading out horizontally near the surface, as they are compelled to do in a thin soil, and are thus secured from the effects of drought. The rain sinks into a deep soil, and is thus preserved to the uses of the crop; while in a thin soil, it runs off, is soon evaporated, or stands on the surface, doing little good in the former cases, and absolute injury in the latter. I should not only plow deep, but I should follow in the furrow of the four horse plow with a good substratum plow, and this with the liming, judicious manuring and proper rotation, I should calculate upon as my security for a good crop, always. I believe this practice to be not only the best preventive of winter-killing and injury from drought, but also of injury from the fly. By this practice you secure a robust constitution to the plant, and, of consequence, thus enable it to withstand, without harm, the pressure upon the sap vessels occasioned by the flax-seed pupa of the fly, as it becomes embedded in its surface. In illustration of the good effects of deep plowing, I will refer to the practice of *garden culture*. Who ever doubted that deep spading—even two or three spits deep—was not only useful, but necessary to success? And in what does a garden differ from a farm? In size—nothing else.

Manure cannot always be obtained, nor can enough be made by every one for the whole farm. But a vast amount may be obtained and made, more than is now usually done. By a little management, the manure now made may be increased in value, without increase of quantity. Properly constructed manure pits should be prepared, with shed roofs to protect their contents from the effects of rain and sunshine. All manure should be deposited in the pits while *fresh*—before the rain has washed away its salts, or the heat of the sun evaporated its volatile principles. Every kind of vegetable and animal offal should be thrown into the manure pits. The pits should be so situated near the barn or under it, that they would receive the urine of all the animals. There should be two pits, that the contents of one might be digesting, while the other was receiving materials. The mode of preparing the manure, time of applying it to the land, the quantity to be applied to the acre, the mode of application, &c. &c., are, and of necessity must be, left to the discretion of the farmer. There is, however, one kind of manure that I think is too much neglected, and it is often the only one that can be made available. I allude to turning in green crops. Turning in a clover lay for this purpose, is common enough; but I think the object may be attained more quickly by turning in crops of corn sown broadcast. Two, if not three crops of corn, could be grown and turned in, in the course of a season. That this kind of manure should afford all the benefit of which it is capable, the land should have been previously limed; or, if not previously done, a good dressing of lime should be turned in with the young corn.

General principles suit all, and the details of their application must be varied to suit each particular case. In conclusion, theoretical knowledge is invaluable to a farmer, as it is to all other professions, but it requires practical knowledge, intelligent perseverance, and untiring industry, to carry out its principles and produce their full effects.

GIDEON B. SMITH.

From the Columbia Planter.

FAIRFIELD DISTRICT, Sept. 12, 1843.

Dear Sir—The labor of the manuring system consists in the accumulating process, and the transportation and distribution. The first I regard as a mere bagatelle, compared with the latter, owing to the interference of the peculiar system of agriculture pursued in this district; one which, while I dislike it, I cannot discard. As my chief opposition to it grows out of its conflicting with my manuring operatins, it will be relevant to my subject to explain my objections in the course of my remarks; and this I shall do in the hope that some one of your patrons, more inventive than myself, may be able to obviate my difficulties.

I have a cow-house, 100 feet long by 25 wide, which stands in the midst of an enclosure 150 feet by 75. A part of the house is divided into stalls for milch cows; another portion is cut off for calves, and the rest is left open for the *ignobile vulgus*. Each division has its proportion of unsheltered area, so as to obviate the evil of personal rencounters, which would necessarily grow out of too close contact. The loft is floored in its whole extent, and affords ample room for a sufficiency of shucks. As soon as my "pen" is emptied in the early part of the spring, I recommence to "trash it," and for that purpose I employ two tilt-carts, each with an appointment of two boys and a woman, in conveying leaves from the woods. The former load and drive, the latter rake. I do not use hoes in collecting the leaves, but rakes with open teeth, less I impoverish and expose the earth, so as to cause the trees to die. My carts are supplied with high moveable frames, formed of light laths, to enable them to carry a quantity consistent with the trifling weight of the material.—When I have covered the area of my pen with one layer of leaves closely placed, I level them, clean out my stables, which have been also "trashed" from time to time, and distribute the contents over the whole surface. I then hasten to cover over the whole pen with another layer of leaves, so as quickly to exclude the stable manure from the sun. I also re-litter my stables promptly, for it is essential, in my opinion, to have a layer of stable compost to intervene the successive strata of litter from the woods. In the meantime, too, my cattle are nightly collected in the pen, and are fed on shucks and straw, which are daily thrown into racks that run through the centre of the house.

Thus I go on till necessity compels me to remove my mules from the cart to the plow. In the past and several preceding seasons, as soon as my crop has been planted, I have again started one cart, two boys and a woman, at the trashing of my pen, and the removal to it of the compost from the stables. Always in the latter part of July, I start another cart, properly officered, and keep them both steadily at the work till the wasting of my cotton in the fields compels me to reduce my "trash force" to one-half. In the month of September, I usually make a pen in a neighboring field, which is "resting," and which I wish to manure the next year, and trash and pen my cattle upon it till the commencement of winter. As soon as my cow-house pen is thus abandoned, I employ all my wagons, and as many laborers as are necessary to keep them in incessant motion, in removing the deposits from it to what I call my "manured field," one which I have nourished highly and worked hard for many years, and which, like a well trained gladiator, improves gradually under the treatment. The compost thus carried into the field is thrown into a conical heap, in a central position, and covered with "raw trash" or straw. I now suffer the surface of my cow-house pen to dry and indurate, ready for the new crop of leaves, otherwise it becomes wet, soft and boggy, in winter.

In winter I recommence to trash it, and desert my "fall pen." I now have my main stock of manure deposited in its proper field, and my "fall pen" perfected in my fancy field of the year; and I consider the first process of the system complete. All this I have regarded as nothing—but now comes the real difficulty.

In find, Mr. Editor, that I shall have to divide my subject into three parts; the first embracing what I have already written; the second the transportation and minute distribution of the manure; and the third, its effects. To each of these heads I will devote a chapter, and I therefore close my regular treaties for the present; but as my paper is not filled, I will indulge myself with a short digression.

If you feel a curiosity to ascertain how little the generous soil of Fairfield has been requited for her bountiful production, visit her, and take an inventory of the rakes, horse-carts, and well littered cow-pens and stables, to be found within her borders; and observe how the food her fields so much crave is suffered offensively to cumber and pollute the lanes which lead to the dwellings of her improvident and ungrateful inhabitants. The offence to your olfactory nerves would be lost in your sorrow that you had found an illustration of the fact, that pearls are sometimes cast before swine; for a thing unclean in itself may be rendered "a jewel" by its usefulness, and the "lords of creation" may remain as unwise as "the beasts of the fields," by their neglect of reason, the attribute of man. I take this censure as freely to myself as I bestow it upon others, for I have left undone much more of what I know to be practicable, than I have accomplished.

Yours, &c.

FARMINGTON.

CHICKEN HATCHING.—Some enterprising persons in Brooklyn, L. I. have established an Institution in that city for the purpose of hatching chickens on a large scale, which is dignified with the name of Polotokion. It comprises five or six long buildings, and several acres of land.

They have a similar affair in England called the Eccaleobeion, which is in successful operation and turns out one hundred chickens a day. The practice has long prevailed in Egypt, and recently has been introduced in France. Reaumur, we believe, first succeeded in raising chickens by means of the common oven. The modern aparatus consists of a series of flues sup-

plied with hot water. A good deal of care is necessary in raising the *youngsters*, as they do not prove very healthy. It is said they have to be taken care of by the old hens for at least a month after they are hatched.

From the American Eagle.

Mr. Editor—The following article, which I find in an old paper published in 1797, I think will be read by many of your subscribers with interest—and I am sure that many of our citizens, both in the city and country, would be benefitted by adopting somewhat a similar course of retrenchment and reform. A Farmer.

CAUSE OF AND CURE FOR "HARD TIMES."

I profess myself to be an honest farmer, for I can say that no man could ever charge me with a dishonest action. I see, with great grief, that all the country is afflicted as well as myself; every one is complaining, and telling his grievances; but they do not tell how their troubles came on them. I know it is common for people to throw the blame of their own misdeeds upon others, or at least to excuse themselves of the charge. I am in great tribulation; but to keep up the above character of an honest man, I cannot in conscience say that any one has brought my troubles on me but myself. "Hard times and no money," says every one. A short story of myself will show how it came "hard times and no money" with me, at the age of 55, who had lived well these forty years. My parents were poor, and they put me, at twelve years of age, to a farmer with whom I lived until I was twenty-one. My master fitted me out with two stout suits of homespun, four pair of stockings, four woolen shirts, and two pair of shoes.

At twenty-two I married me a wife, and a very good woman she was. We took a farm of forty acres on rent. By industry we gained ahead fast; I paid my rent punctually, and laid by money. In ten years I was able to buy me a farm of sixty acres, on which I became my own tenant. I then in a manner grew rich and soon added another sixty acres, with which I was content.

My estate now increased beyond all account. I bought several acres of outland for my children, who amounted to seven, when I was forty-five years old. About this time I married my oldest daughter to a clever lad, to whom I gave one hundred acres of my outland. This daughter had been a dutiful, working girl, and therefore I fitted her out well, and to her mind; for I told her to take of the best of my wool and flax, and to spin her gowns, coats, stockings and shifts; nay, I suffered her to buy some cotton and make into sheets, as I was determined to do well by her. At this time my farm gave me and my whole family a good living on the produce of it, and left me one year with another one hundred and fifty silver dollars, for I never spent more than ten dollars a year, which was for salt, nails and the like. Nothing to wear, eat or drink, was purchased, as my farm provided all. With this saving I put money to interest, bought cattle, fattened and sold them, and made a great profit. In two years after, my second daughter was courted. My wife says—come, you are now rich; you know Molly had nothing but what she spun—and no other clothing has ever come into our house for any of us; Sarah must be fitted out a little. She ought to fare as well as neighbor N——'s Betty. I must have some money and go to town. Well, wife, it shall be as you think best—I have never been stingy; but it seems to me that what we spin at home will do.

However, wife goes to town and returns in a few days with a calico gown, a calamanco petticoat, a set of stone tea-cups, half a dozen pewter teaspoons, and a tea kettle—I did not feel it; and I confess I was pleased to see them; Sarah was as well fitted off as any girl in the country.

In three years more my third daughter had a spark; and the wedding being concluded upon, wife comes again for the purse; but when she returned, what did I see! A silken gown, silk for a cloak, a looking glass, China tea-gear, and a hundred other things, with the empty purse. But this is not all, Mr. Editor. Some time before the marriage of this last daughter, and ever since, this charge increased in my family, besides all sorts of household furniture, unknown to us before; clothing of every sort is bought—and the wheel goes only for the purpose of exchanging our substantial cloth of flax and wool, for gauze, ribbons, silk, tea, sugar, &c. My butter which used to go to market and brought money, is now expended at the tea-table.—Breakfast, which used to take ten minutes, when we were satisfied with milk, or porridge made of it, now takes my whole family an hour at tea or coffee. My lambs, which used also to bring cash, are now eaten at home—or, if sent to market, are brought back in things of no use—so that, instead of laying up one hundred and fifty dollars a year, I find all my loose money is gone—my best debts called in and expended—and being straightened, I cannot carry on my farm to so good advantage as formerly, so that it brings me not near so much; and further, what it cost me to live, (though a less family than heretofore, and all able to work,) is fifty or sixty dollars more than all my farm brings me in. Now, this has gone on a good many years, and has brought hard times into my family: and if I can't reform it, ruin must follow—my land must go. I am not alone; I know of thirty or forty who have gone hand and hand with me; and they all say "hard times." Now, Mr. Editor, I do not know how you live—may be you are more frugal than we are, as all used to be; but I am still master in my own house.

I am determined to alter my way of living to what it was twenty years ago, when I laid up one hundred and fifty dollars a year. I know I can do it, for I have got all my land yet; I will increase my sheep, my flax ground and my orcharding: my prudence brings (scarce as money is) as much as it used to do. Not one thing to eat, drink or wear, shall come into my house, which is not raised on my farm, or in the country, except salt and iron work, for repairing my buildings and tools—no tea, sugar, coffee or rum. The tea-kettle shall be sold. I shall then live and die with a good conscience. My taxes, State and county, which appear now intolerable, will then be easy. My young children and my grand children will see a good example before them; and I shall feel happy in seeing a reform of abuses which have been growing on me for twenty years. If you will tell my story, it may work some good, and you shall have my lasting thanks.

How to be Rich.—The secret is not in earning, but in saving—almost any man can earn money, but few can keep it. A small sum is disregarded; yet a large one is only several small ones united; unless little ones are laid together, how can there be a great one?

Suppose a person save a cent a day—at the end of one year, he has three dollars and sixty-five cents—at the end of 20 years, one hundred dollars, including interest. How easy it is for a man to save a cent a day; how many can save ten cents a day—or thirty-six dollars and fifty cents a year—or about one thousand dollars in 20 years, including interest?

He who spends seven cents a day upon some idle fancy—for instance, in drink, cigars, fruit, &c., should at the same time reflect that he thus throws away the interest of a dollar a year.—Are there not often occasions in the course of a day, when a person spends three cents, two cents, or one cent, which he might avoid, without feeling the worse for it? Then goes his ten cents a day—his one thousand dollars in 20 years—the very interest of which would afford him and his heirs, a clear profit of seventy dollars a year. Many grow rich by saving, with but very little faculty for earning; some old men who have always lived well, are very rich from mere saving, who did not earn so much daily, as their poor neighbors.—*Maine Farmer.*

From the S. C. Temperance Advocate.

Mr. Editor—The following was prepared for the Newberry Agricultural Society, in August, 1842, but owing to the press of other matters, it was not read. I have to-day accidentally laid my hands upon it. I send it to you for the Advocate.

October 6th, 1843.

—

The undersigned having intended to compete for the prize for wheat, but having, by some strange mistake, supposed that the result of an acre was required for that purpose, when in point of fact five acres should have been measured, ascertained alone the product of a single acre. But as he thinks his crop was improved by the mode of culture, he begs leave to state the same, and the result, so that if there be any thing of value in it, his brother farmers may have the benefit of it.

The first week in October, eighteen bushels of Holland wheat, and two bushels of Black Sea wheat, well saturated with blue stone, were sown upon about twenty acres of land. Eighteen acres had been in cultivation about eleven years. The other two acres were very old land. All of it was stiff red land. Upon the whole was sown cotton seed, at the rate of about twenty bushels to the acre, except upon the two acres of very old land; upon that was sown about a wagon load of cotton seed; here the Black Sea wheat was sown; the seed of it was mixed and very inferior, having for the two preceding years had the rust. The whole was plowed in and then rolled. In February, five bushels of slacked ashes per acre were sown upon the wheat An Acre of the Holland Wheat was selected and measured; it produced twenty bushels and one peck. The whole crop of Holland wheat was two hundred and three bushels, and that of the Black Sea wheat twenty two bushels. The latter was not at all affected by the rust. The rest of the crop was slightly affected by it. Whether the exemption of the Black Sea wheat from rust, this year, is to be ascribed to the large quantity of cotton seed sown, will require further experiments to decide. The value of the dressing with ashes was very apparent, and I am persuaded double the quantity per acre would answer still better.

In December, I sowed a small quantity of wheat, the toll of some ground for Col. Peter Hair. It was sown in cotton ground. The greater part of the seed was rolled in wet lime so as to incrust the seed; as far as that extended there was not the least smut. Three or four lands were sown with the seed, without being rolled with lime, and they were full of smut.—This little experiment goes far to show that lime is an antidote to smut. The wheat grew vigorously, and made an ordinary average crop of wheat for this section. I am persuaded that a little attention to the culture of wheat will, in a few years, enable us to raise our average crops, from eight to twenty bushels per acre.

John Belton O'Neall.

August, 1842.

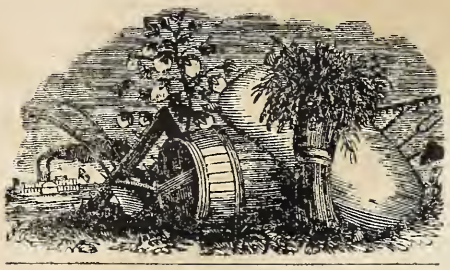
THE FARMER'S CREED.

Let this be the Farmer's creed—
Of stock, seek out the choicest breed;
In peace and plenty let them feed;
Your land sow with the best of seed;
Let it not dung nor dressing need—
Inclose and dress it with all speed,
And you will soon be rich indeed.

Farmers' Cabinet.

Immense Product.—We learn, says the National Intelligencer, that Hill Carter, Esq., of Shirley, on James river, Va. reaped from 160 acres, 5280 bushels of wheat, averaging 33 bushels per acre! This is unequalled in Virginia agriculture. His whole crop of wheat, on 270 acres, reached the large quantity of 8000 bushels, being an average of nearly 30 bushels per acre.

At Westover, the seat of John N. Selden, Esq., on James river, 100 acres of wheat averaged 30 bushels per acre; also a noble product.



WEDNESDAY, NOVEMBER 8, 1843.

BACK NUMBERS.—All new subscribers to the "Southern Cultivator" can be supplied with the back numbers.

HANCOCK FAIR.

To give place to the proceedings of the Fair of the "Planters' Club of Hancock," which reached us just on the eve of publication, we have excluded any comments of our own upon that or any other subject. We rejoice, however, to see the spirit which these Fairs seem to be exciting through the country.

ANNUAL FAIR OF THE PLANTERS' CLUB OF HANCOCK.

SPARTA, November 3d and 4th, 1843.

Messrs. Editors—The Executive Committee of the Planters' Club of Hancock, transmit to you for publication, the following synopsis of the proceedings on the days of the Annual Fair.

The Club convened at the Female Academy, on Friday the 3d, where a large concourse of citizens of this and other counties were present, to witness the exhibition of stock of various kinds, domestic fabrics, &c., which were examined by various committees; and on Saturday, the 4th, the committees reported, and premiums and honors were awarded, and an interesting address was delivered by ELI H. BAXTER, Esq., to a large collection of ladies and gentlemen.

The premiums and honors awarded were—

To Wm. Dickson, Jr., $5 for the best acre of corn, 73¼ bushels, on low land, without manure.

To Thomas C. Grimes, $3 for the second best acre of corn, 62 bushels, on old up land, medium quality, soil red clay, manured with stable manure; coltered, and planted 1st April.

Capt. R. S. Hardwick showed a fine specimen of wheat, weighing 71¼ lbs to the bushel, and yielding 42 lbs. superfine flour.

HORSES.

To Thos. Neal, of Warren county, $5 for his bay horse Wonder, 4 years old, by Pennoyer, from Old Nubbin.

To James B. Edwards, $3 for his bay horse, by imported Coronet, dam by Chanticleer.

To Thomas C. Grimes, $2 for his filly, 2 years old, by Singleton, dam Sally Word.

To James McCason, $1 for his filly, Miss Bethune, 2 years old, by Stanley, dam a Galatin mare.

To Wm. T. Brooke, of Taliaferro, $2 for his sucking colt, Miller the Prophet, by Wonder, out of a Janus mare.

To Thomas Neal of Warren county, $1 for his colt by Wonder.

To Col. John Lamar, of Bibb county, $5 for his brood mare, Bonny Bess, by Sir Hal, dam Coquette, by Sir Archer.

To Capt. R. S. Hardwick, $2 for his mare Jane Wiley, by Baron Trencke.

To Thomas Neal, of Warren county, first honor, for his bay mare Lucinda.

To Wm. T. Brooke, of Taliaferro county, second honor, for his roan mare Fire Tail.

The Club examined a Jack, the property of Wm. Daniel, of Greene county, 2 years old.—They regard him as one of the finest animals of his race, either as to form or size.

CATTLE AND SHEEP.

To Col. John Bishop, $5 for his bull Red Jacket, Ayreshire and native.

To Thos. C. Grimes, $2 for his Bull, John C. Calhoun, Patton stock.

To Thos. C. Grimes, $5 for his cow, Red Sally, and calf, Patton stock.

To Capt. R. S. Hardwick, $2 50 for his cow, Spot, native stock.

To Capt. R. S. Hardwick, first and second honors, for his cows Flower and Bet.

To Capt. R. S. Hardwick, $2 for his roan heifer Eliza, 2 years old, half Durham.

To Capt. R. S. Hardwick, $1 for his red heifer, half Durham.

The Club deem it their duty to state, that a very fine Bull, full blood Durham, bought of Col. John Lamar, of Bibb county, by R. S. Hardwick, was shown them, but no premium being given on such, can only bestow upon him their highest commendation. The Club deem it proper also to state, that a fine Bull, the property of Col. W. C. Dawson, of Greene county, and thorough bred Durham, by Denton, was shown by Capt. Hardwick, but not coming within the rules of the Club, (his owner not being a member,) he was not permitted to take a premium.

To Capt. R. S. Hardwick, $2 for his South Down Tup.

To Capt. R. S. Hardwick, $2 for his South Down Ewe.

SWINE.

To Col. John Bonner, $3 for his fine Berkshire Boar, Ontario.

To Col. John Bonner, $2 for his fine Berkshire Boar, Great Western.

To Col. John Bonner, first honor for his fine Berkshire Boar, Rip Van Winkle.

To Capt. R. S. Hardwick, second honor for his fine Berkshire Boar, Jemmy Redding.

To Col. John Bonner, $3 for his fine Berkshire Sow, Black Rose.

To Col. John Bonner, $2 for his fine Berkshire Sow, Lady Huddlesion.

To Capt. R. S. Hardwick, first honor for his fine Berkshire Sow, Shakeress.

To Col. John Bonner, second honor for his fine Berkshire Sow, Myrtis.

To Col. John Bonner, third honor for his fine Berkshire Sow, Victoria.

To John W. Moody, of Oglethorpe county, $2 for his Berkshire Pig, Miss Fisher.

To Col. John Bonner, $2 for his Berkshire Boar Pig.

To Col. John Bonner, first honor for his second best Pig.

To Capt. R. S. Hardwick, second and third honors for his fourth and fifth best Pigs.—(The pigs were between 6 and 12 months old.)

There were no hogs exhibited as fat hogs between one and two years old. Wm. H. Sayre exhibited four fine shoats, 11 months old, estimated by the Club to weigh 250 lbs each nett.

DOMESTIC FABRICS, &C.

To Miss Persons, of Warren county, $3 for a White Counterpane, in imitation of a Marseilles Quilt.

To Mrs. C. Battle, $2 for a Counterpane.

To Miss E. Beall, of Warren county, first honor for a fancy Counterpane.

To Mrs. M. Battle, second honor for do do do

To Miss A. L. Battle, third honor for do do do

The Club cannot but notice here, that there were a number of other beautiful Quilts and counterpanes, and regret that they cannot have premiums awarded them.

To Miss A. M. Kelly, $3 for a piece (10 yards) of Homespun, for gentlemen's wear.

To Mrs. Baxter, $2 for do. do. do.

To Miss Worthy, first honor for a piece of Homespun, for gentlemen's wear, which but for a deficiency in quantity, would have received a premium.

To Miss Bass, second honor for do. do. do.

To Mary J. Harris, 3d honor for do. do. do.

To Miss E. Beall, of Warren county, first honor for the best piece of manufactured Domestic Silk, in a handsome fancy reticule.

To Mrs. Lanier, first honor for a specimen of Sewing Silk.

To Mrs. Dudley, of Washington county, first honor for a handsome Table Cover.

To Mrs. Baxter, first honor for a piece of Carpeting.

To Mrs. Bird, second honor for do. do.

To Miss Arnold, first honor for a net Shawl.

To Miss Worthy, second honor for do. do.

To Miss Gordy, third honor for a wove do.

To Mrs. Simmons, first honor for a Toilet Cover.

To Mrs. Hardwick, over 70 years of age, first honor for a pair of Hose.

To Miss Sarah Baxter, first honor for a pair of Gloves.

To Mrs. Lanier, first honor for a Net Collar.

To Miss Brooking, first honor for a Lace Ruffle.

To Mrs. Bird, first honor for a specimen of rich Butter.

To Mrs. Bird, first honor for a specimen of very white and clear Tallow Candles.

James Smith and Marcellus Simmons each presented samples of Molasses made from corn stalks, rich and of fine flavor.

Messrs. Watkins & Hart presented some beautiful specimens of Tin Ware.

The officers of the Club for the ensuing year are—

BENJ. T. HARRIS, President,
JOHN BONNER, 1st Vice President,
R. S. HARDWICK, 2d Vice President,
A. E. W. Brown, 3d Vice President,
T. H. AUDAS, Secretary and Treasurer,
N. C. SAYRE, Corresponding Secretary.

Resolved, That the Secretary, under the direction of the Executive Committee, prepare a concise report of the proceedings of the Club at this Fair, and have it published in the Southern

Cultivator, the papers at Milledgeville, and the Sandersville Telescope.

In all which you will perceive that we are still persevering, and mean to continue in the great cause of improving our minds, our crops, and our stock, and producing whatever we can, that we may, as far as possible, become the exporters of the necessaries of life, and not the importers as we now are.

TUTTLE H. AUDAS, Sec'y.

EDEN, EFFINGHAM COUNTY, October 17, 1843.

Messrs. Jones—Much has been said upon the subject of plowing in green crops for manure, and as I place much more confidence in actual experiments in the field than in theory, I have made some for my own satisfaction, and as they may be useful to others, I give them to you to be disposed of as you please.

My experiments were made on level, sandy, pine land, which, when fresh, did not produce more than twelve bushels of corn per acre, and when last planted did not produce more than six or seven, and had not been planted for three years, but had been used as a calf pasture, and had become partially set with broom sedge.—Most of this field I planted about the first of July last year, in peas, which, owing to the poverty of the land and a dry season, did not grow well, but were suffered to mature and were eaten off by hogs. From this I staked off one acre for my experiment, which I will call No. 1.—Adjoining this acre I staked off another, which was not planted in peas, and was not plowed up until after it was planted this spring, say No. 2. Adjoining this I staked off another acre and sowed it in cow peas, broadcast, about the 15th of July. They came up and grew well, for such land, and about the last of September, when the peas were in full bearing, and some of the leaves began to fade, I had them plowed in—this is No. 3. Adjoining this I had another acre plowed up at the time I planted No. 3, turning in the weeds, grass and broom-sedge—this we will call No. 4; and adjoining this again, I had another acre plowed in November, after the frost had killed the weeds, &c.—this is No. 5. All this field was planted this spring in corn, and cultivated exactly alike. I have just gathered it and here is the result:

No. 1. Planted in peas and eaten off by hogs, gave	11¼	bushels.
No. 2. Remained unbroken until planted	7½	"
No. 3. Planted in peas and plowed in	10½	"
No. 4. Plowed about the 15th July.	8¼	"
No. 5. Plowed in November	9	"

From which it will be seen that the acre planted in peas and eaten off by hogs, gave the greatest yield, and the acre not plowed until after it was planted this spring, the smallest.—This last I do not believe would have been the case if the land had not been rested more than one or two years; for I believe that when our land gets set with broom-sedge it ceases to improve, and the dry broom-sedge plowed in, in the spring, decays so late as to be of no service to the crop. The piece plowed in July is the next lowest. This, I think will be of great service to me, as I have been in the habit as soon as I finish plowing my crop, to commence breaking up my land for the next crop, believing that turning in the weeds &c., in a green state would improve the land, but I am now convinced that turning up and exposing the land to the sun, at this hot season of the year, does it more injury than the weeds turned in does it good; and besides it is harder on my mules and plow hands than any other plowing they have to do. The system of planting peas for stock, I am glad to find, is best for the land, as it not only improves the land, but gives us a crop of peas for our labor.

I may, at a future day, give you my method of planting peas, as it may be of service to young planters.

Very respectfully, yours,

C. POWERS.

The fattest oxen at the New York State Agricultural Fair were exhibited by Jeremiah Brown, of Orleans county. There were three of them, weighing severally 3200, 3800 and 4000 pounds.

We regret to learn by the following from the *Columbia (S. C.) Planter*, of the 25th ultimo, that the proprietors of that paper have been compeled to discontinue its publication:

It is with regret that we announce that this Paper has so far failed to obtain the patronage which we were encouraged to expect when commencing it, that we cannot afford to continue it, on its present footing. We therefore suspend its publication until the meeting of the State Agricultural Society, when an effort will be made to raise it to a better condition. Should that effort succeed, it will be immediately resumed—otherwise, the money that has been paid for subscription beyond the present time will be returned.

The National Intelligencer has the following description of a simple invention by Dr. McWilliams, of that city, for gathering fruit:

The "Fruit Gatherer" is an instrument designed and well adapted for plucking fruit from the tree where it cannot be reached by the hand. The fruit is gathered from all the branches without the slightest injury to either the tree or fruit, and in the most delicate manner. It plucks off all sizes of fruit, from a cherry to the largest apple. It is easy of construction or repair, and the expense trifling. A lady or gentleman in their garden or orchard, standing on the ground, may select such fruit as is wished and obtain it without disturbing that adjacent. This instrument accomplishes perfectly what has frequently been attempted both in Europe and this country in vain.

FALL AND WINTER PLOWING—As occasion may offer through the fall and winter, plow up your stiff clayey grounds, which may be destined for spring crops. But be sure *never to plow when the land is wet*, as when turned up in a state of mortar, it will so remain during the ensuing season, and probably will receive no benefit from the breaking down influence of freezing and thawing. If you desire to derive the melioration contemplated, your ground must be in a good condition when plowed. Besides the improvement of texture in the soil derived by fall and winter plowing, much time, which is always precious in the spring, may be thereby gained at that season of business, but even this latter advantage will be lost to the farmer, or planter, unless he see that his ground is in a proper condition when plowed.—*Amer. Farmer.*

In Mr. Webster's Rochester speech occurs the following beautiful thought, as beautifully expressed:

"Gentlemen, every body knows that the foundation of all that is important in human life, lies this great business—the cultivation of the earth. If it were for his sins that man was condemned to till the land, it was the most merciful judgment that Almighty benignity could have inflicted upon him!"

From the Southern Planter.

IMPROVING OLD LANDS.

Mr. Editor—At the request of a friend, I wrote to Dr. R. D. Palmer, desiring him to communicate any knowledge which he had derived from experience as to the best mode of improving our old lands. I send you for publication what he says on the subject, as he gave me permission to do so if I thought any one might be benefited by it. It is evident that we shall have to resort to this or some other mode for restoring our worn-out lands. From my own experience and observation, I feel no hesitation in saying, that I believe the Doctor's plan to be the most practical and economical I have seen suggested.

J. MORTON.

Spring Grove, Campbell, Aug. 11, 1843.

In 1827, I settled on a farm of 560 acres, in the lower end of Campbell county, in the most exhausted condition of any, perhaps, in the State of Virginia. It had been under the very worst system of management from the time of its settlement in 1755. The soil being red, its aspect generally was more that of a gully-side than any thing else. Hundreds of gullies were everywhere to be seen, some from forty to fifty feet wide, and as deep as a common house-top. The previous occupant had annually expended from one to two hundred dollars for corn. An intelligent lady remarked to me that "the land was so thin that we would have to double it."

From this appalling picture the question will naturally arise, "why did you purchase?" The answer is, that "I thought it a suitable stand for the practice of medicine, and that from some eighty or ninety acres of creek bottoms I should be able to draw a support until the exhausted land could be reclaimed."

At first I divided the farm into four equal shifts, and cultivated in corn, followed by wheat, where the land was thought to be good enough to produce it, and where not, in oats or rye. In consequence of the great poverty of the soil, rye was generally preferred, as oats would not grow high enough to be cut. My aim, from the first, was to clover and plaster all of the land in small grain; but, from the paucity of my means, much could not be done in that way for several years. Experience soon taught me that one-fourth of my land would not produce enough to support my family of ten or twelve in number; and that the better way would be to resort to a ring-fence, and cultivate the flat land and such places as required cleaning up, while I was manuring the thinner parts of the farm. My aim has ever been to raise as much manure as I possibly could, without neglecting other necessary things; and always to haul out in the spring. The principal resources have been from corn-stalks, leaves, straw, &c. When put in the stables and farm-pens they afford comfortable beds to the horses, cattle, &c., while, at the same time, they absorb and retain the liquid manure, which otherwise would be lost.

The present condition of my farm will tell whether my efforts have been in vain.

I should not neglect to say, that as soon as all of my galled land got in a condition to bring grass, I again divided my farm into five, instead of four shifts; and that now we fallow one, so as to have, annually, one in corn and two in small grain.

I made no tobacco until my fields every where, through the assistance of manure, clover, plaster, &c., had taken on a rich mantle of green.

The first object of the farmer, in reclaiming

worn-out lands, should be to extend his manures so as to get as much stock in grass as he can. For this purpose I think top-dressing answers the purpose best. A mixture of red clover, herdsgrass, timothy, greensward seed, &c., with plaster of Paris, sown late in February or early in March, so as to put a bushel of plaster to the acre, will generally stick well, especially if the thinner places have a little top-dressing. But little grazing should be done except on the field intended for corn the ensuing year; and that, principally, after the full blossoming of the clover.

As time and leisure may be afforded me, from the pressure of my engagements, I may address you on some of the individual branches hinted at in the foregoing desultory epistle.

Very respectfully,
R. D. PALMER.

A VIRGINIA FARM.

A corresponnent of the Boston Traveller, writing from the valley of the Shenandoah, last autumn, gives the following account of the Steenbergen farm, situated in that valley, some 40 miles above Winchester. Few parts of the United States afford examples of more fertile soils, and few instances of better cultivated farms than the rich valley of the Shenandoah.

"On ascending the opposite bank of the river we entered the extensive grounds of the celebrated Steenbergen farm, a view of which is worth a day's journey in more oppressive heat than we experienced to-day. The farm consists of 7000 acres, a large portion of intervale or bottom land, and nearly the whole is under cultivation. The family mansion is beautifully situated on rising ground, overlooking the whole area, and the farm houses are conveniently arranged in the vicinity for the overseers and slaves. The hay crop was gathered, and the quantity may be judged from the fact that from 1500 to 2000 head of cattle are kept on the premises. The wheat too, between 400 and 500 acres, had been harvested, and much of it was already threshed and sent to market. Our road passed through a luxuriant field of corn, nearly ripe, embracing a level tract of 600 acres, and a richer sight for the lover of scientific husbandry I have never seen. Mr. Steenbergen, who owned this unrivalled farm, and by his agricultural skill, extraordinary energy and perseverance, in a few years greatly improved the strength of the soil, rendered the property more valuable, probably, than any other farm in the United States."

We may add here, as a warning to others, that not satisfied with his farm, Mr. S. became infected with the speculating notions at one time so prevalent; that he was with many others unfortunate, and when he failed some three or four years since, his liabilities amounted to more than a million and a half, of which about $650,000 was to the United States Bank. Mr. S. is now a resident of La Porte, Ind., and his farm has passed into the hands of Mr. Munn, of Lynchburg, Va.

"Such as have virtue always in their mouths and neglect its practice, are like a harp, which emits a sound pleasing to others, while itself is insensible to the music."—*Diogenes.*

AUGUSTA MARKET.

Cotton—The market for a few days has been very active, and large sales have been made at an advance of ⅛ to ¼ cent ℔ lb. on all descriptions. We now quote 6 @ 7¼ cents as extremes of the market—remarking that it requires an extra prime article, in the best possible order, to command our highest figures, while the principal sales are 7 @ 7¼ cents.

Dry Goods, Groceries, &c.—Business among our merchants wears the appearance of considerable activity, and they seem to be sending a large amount of goods to the country, at prices which give satisfaction. The stocks of goods appear large and well selected.

Exchange—The rate for Exchange is ½ ℔ ct. premium on New York and the Northern cities, and par on Charleston and Savannah. Central money continues at 6 @ 7 per cent discount.—We hear of large sales of State Bonds at 76 cents.

AUGUSTA PRICES CURRENT.

GARDEN AND FIELD SEED.

A GENERAL assortment of fresh and genuine GARDEN and FIELD SEED, among which are the following:

Red and White Clover,
Blue and Green Grass,
Rye and Orchard do.,
Timothy and Herds do.,
Millet and Lucerne do.,
Seed Corn of every valuable variety,
Seed Wheat,
Buckwheat and Potato Oats,

Kept constantly on hand by the subscriber, all of which are offered for sale at very moderate prices. All orders, by mail or otherwise, executed with neatness and despatch.

WM. HAINES, JR.,
No. 232 Broad street, Augusta, Ga.
August 30. 18-tf

TURNEP SEED.

A SUPPLY of the following varieties of fresh TURNEP SEED just received, viz:

Yellow Sweedish or Ruta Baga, very fine for stock,
Large Globe Turnep, } Fine
" White Flat do. } for
" Hanover or White Ruta Baga do } table
" Norfolk do. } use.

For sale in quantities to suit purchasers, by
Aug. 30 18-tf WM. HAINES, JR.

BOMMER'S PATENT MANURE.

THE undersigned is the Agent of Messrs. Abbett & Co., for vending rights to individuals for making and using the above named Manure. By reference to the following advertisement of Messrs. Abbett & Co., the prices may be ascertained. All orders addressed to me, *post paid*, at Sparta, Ga., will receive prompt attention.
Aug. 30. 18-tf R. S. HARDWICK.

THE BOMMER MANURE METHOD,

WHICH teaches how to make vegetable manure without the aid of live stock, in from 15 to 30 days, by a course of humid fermentation set into action at a cost of from 50 cts to $4.

And also to make Compost *in a few days.* And how to make a rich fertilizing liquid called "purin," having all the strength without the acrid qualities of urine.

With the view of graduating the cost to the quantity of land upon which it may be desired to use the method, the following scale of prices has been adopted, viz:

For Gardens of any extent $6
Farms up to 100 acres 10
" from 100 to 200 acres 15
" " 200 to 300 " 18
" " 300 to 400 " 20
" over 400 acres in any one farm ... 25

By the remittance of the sum here specified, a copy of the method will be sent by mail or in any other mode proposed by the purchaser.

All letters of inquiry must be post paid.
ABBETT & CO., Baltimore,
Proprietors of the patent right for the Southern and Western States. aug 16

THE SOUTHERN CULTIVATOR

IS PUBLISHED BY

J. W. & W. S. JONES,

And will be issued every other Wednesday, at ONE DOLLAR a year, INVARIABLY IN ADVANCE. The CASH SYSTEM will be rigidly adhered to, and in no case will the paper be sent unless the money accompanies the order.

ADVERTISEMENTS pertaining to agriculture will be inserted for ONE DOLLAR for every square of TWELVE lines, or less, for the first insertion, and SEVENTY-FIVE CENTS per square for each continuance.

☞POST MASTERS are authorized to receive and forward money free of postage.

☞ALL COMMUNICATIONS MUST BE POST PAID

SOUTHERN CULTIVATOR.

VOL. I. AUGUSTA, GA., NOVEMBER 22, 1843. No. 24.

PRIZE ESSAY.

THE PREPARATION AND USE OF MANURES.

BY WILLIS GAYLORD,

(Concluded from page 171.)

LIME.

There is no substance, containing no animal or vegetable matter, which exercises a more powerful or beneficial effect than lime, in some one or all of its forms of carbonate, phosphate and sulphate. In the common form in which it is found, that of carbonate, it acts in two ways, mechanically and chemically. Being less porous than sand, and more so than clay, its mixture improves soils in which either of these prevail; while as an alkaline earth, it acts chemically on such animal or vegetable matters as may exist in the soil. Lime developes its chemical action most fully when in its caustic state, or when, by burning, the carbonic acid has been expelled, and the lime rendered what is termed quicklime. In this state, it dissolves such organic matter as may exist in soils, and prepares it for the food of plants. Humus frequently exists in the soil in a solid and insoluble state; lime applied to this renders it soluble in water, in which form it may be taken up by the roots of plants. A vast deal of needless controversy has been carried on respecting the value of lime as a manure, or the quantity which should be used per acre. By some, it has been extolled as the very highest on the list of effective manures; while others have decried it as of no use whatever; and both have appealed to experiments as establishing their positions. A knowledge of the nature of the action of lime, would have prevented such seeming contradictions. "Lime in excess, forms, from the humus of the soil, an insoluble salt; and may thus, when applied to a soil abounding in salts of lime, or in which it already exists, be productive of injury, whatever may be the vegetable or organic matter of the soil. In this state of excess, lime converts, but at the same time locks up, the humus of the soil; when if applied in the right quantity, it would have been useful.—Lime is of no value whatever as a converter, or produces no chemical effect in promoting growth, unless there is organic matter in the soil on which it can act. Lime is most efficient when used on soils full of insoluble humus, such as peaty matter or woody fibre, but which, from the abundance of the tannin principle contained, resist the ordinary processes of decomposition." There would seem to be no difficulty, therefore, in determining whether lime can be used on any given soil to profit. Indeed there are, it is believed, none where it would not be useful, except such as are already supplied with this carbonate, or those which are wholly destitute of vegetable or organic matter. As a general rule, the greater the quantity of humus in a soil, the greater the amount of lime which may be applied with benefit. As long as there is a store of organic matter in the soil, lime, if not in excess, is a valuable manure; but when this is exhausted, the application of lime only increases the sterility by destroying such efforts at vegetation as might in time, aided by light and moisture, partially remove the unproductiveness existing. This fact may serve to explain some of the conflicting statements that have appeared in the agricultural journals of our country, on the use of lime. Where humus is abundant, the quantity that may be safely used, is very great; on soils already poor, a small portion speedily exhausts the remaining powers of the soil. Lime, from its alkaline qualities, acts in neutralizing whatever free acids exist in soils, whether oxalic, phosphoric, malic, or others. It acts also in decomposing some of the earthy or compound salts formed in the soil, and thus renders the geine held by them available to the plant; but its great and most important use is in converting the insoluble organic matters existing, into soluble ones, and thus directly furnishing an abundant source of nutriment. Carbonate of lime is sometimes used pounded or broken fine; and in this state, its mechanical value is great in stiff or clay soils. Such soils too, usually abound in acids; and these gradually acting on the lime gravel, its chemical effect is slowly but beneficially apparent.

MARL.

Marls, which exert so powerful an influence on many soils, derive most of their value from the lime they contain; and with few exceptions, their power as fertilizers may be measured by the per cent of lime shown on analysis. There are some marls, however, which are an exception to this rule; their value appearing to depend on other matters than mere lime. Of this kind is the celebrated green sand marl of New Jersey, and some other points of the Atlantic coast. In this formation, which acts so powerfully as manure, there is from 6 to 10 per cent of potash; an agent which, on light soils, is scarcely equaled as a manure. In addition to the lime which marl contains, the influence of the proportions of sand and clay, of which the balance usually consists, must be taken into consideration in determining the value of this substance for particular soils. Thus, on heavy or clay lands, marls abounding in sand will be found preferable to those the base of which is clay; and on light or sandy soils, the latter will be much the most useful, the per cent of lime in both cases being alike. Marl should be spread over the surface, and pulverized by the action of air and frost before it is plowed under. When so treated, experience proves it is a most valuable manure, and a single dressing exerts an influence for many years.

PHOSPHATE OF LIME.
